

HS6206

HS6206 2.4G Wireless SOC

V0.7

weizhengchao/yingaowei

2015/4/21

Revision History

Revision	Date	Description
V0.1	Jul 1, 2014	Update from brief version
V0.2	Jul 7, 2014	Update pad location
V0.3	Jul 9, 2014	Update some details
V0.4	Oct 14, 2014	Update maximum power; Update 500Kbps and 2Mbps sensitivity
V0.5	Dec 9, 2014	Add SOP16 and QFN20 package
V0.6	Jan 12, 2015	Update some MCU configuration
V0.7	Apr 21, 2015	Update maximum power; Auto Retransmit register description

CONTENTS

Revision History	2

2.1 Features	16
2.2 Blocks	17
3 RF transceiver	18
3.1 Features	18
3.2 Block	19
3.3 Functional description	19
3.4 Operational Modes	19
3.4.1 PowerDown Mode	21
3.4.2 Standby Modes	21
3.4.2.1 Standby-I mode	21
3.4.2.2 Standby-II mode	21
3.4.3 RX mode	21
3.4.4 TX mode	22
3.4.5 Operational modes configuration	22
3.4.6 Timing Information	22
3.4.7 Air data rate	23
3.4.8 RF channel frequency	23
3.4.9 Received Power Detector measurements	23
3.4.10 PA control	24
3.4.11 RX/TX control	24
3.5 Protocol Engine	24
3.5.1 Features	24
3.6 Protocol engine overview	25
3.7 Protocol engine packet format	25
3.7.1 Preamble	25
3.7.2 Address	26
3.7.3 Guard	26
3.7.4 Packet Control Field (PCF)	26
3.7.5 Payload	27
3.7.6 CRC (Cyclic Redundancy Check)	27
3.7.7 Automatic packet assembly	28
3.7.8 Automatic packet disassembly	30

3.8	Automatic packet transaction handling.....	31
3.8.1	Auto Acknowledgement	31
3.8.2	Auto Retransmission (ART)	31
3.9	Protocol engine flowcharts	33
3.9.1	PTX operation.....	33
3.9.2	PRX operation	35
3.10	MultiSlave	37
3.11	Protocol engine timing.....	39
3.12	Protocol engine transaction diagram.....	41
3.12.1	Single transaction with ACK packet and interrupts	41
3.12.2	Single transaction with a lost packet.....	42
3.12.3	Single transaction with a lost ACK packet	43
3.12.4	Single transaction with ACK payload packet	43
3.12.5	Single transaction with ACK payload packet and lost packet	44
3.12.6	Two transactions with ACK payload packet and the first ACK packet lost.	44
3.12.7	Two transactions where max retransmissions is reached.....	45
3.13	Data and control interface.....	45
3.13.1	SFR registers.....	45
3.13.2	SPI Operation	46
3.13.2.1	SPI commands	46
3.13.3	Data FIFO	48
3.13.4	Interrupt	49
3.14	Register map	49
3.14.1	Register map table	49
3.14.2	BANK0.....	50
3.14.2.1	CONFIG (RW) Address: 00h.....	50
3.14.2.2	EN_AA (RW) Address: 01h	51
3.14.2.3	EN_RXADDR (RW) Address: 02h	52
3.14.2.4	SETUP_AW (RW) Address: 03h.....	52
3.14.2.5	SETUP_RETR (RW) Address: 04h.....	53
3.14.2.6	RF_CH (RW) Address: 05h.....	53
3.14.2.7	RF_SETUP (RW) Address: 06h	54
3.14.2.8	STATUS (RW) Address: 07h.....	55
3.14.2.9	OBSERVE_TX (RW) Address: 08h.....	55
3.14.2.10	RPD (R) Address: 09h	56
3.14.2.11	RX_ADDR_P0 (RW) Address: 0Ah.....	56
3.14.2.12	RX_ADDR_P1 (RW) Address: 0Bh.....	57
3.14.2.13	RX_ADDR_P2 (RW) Address: 0Ch.....	57
3.14.2.14	RX_ADDR_P3 (RW) Address: 0Dh	57
3.14.2.15	RX_ADDR_P4 (RW) Address: 0Eh	58
3.14.2.16	RX_ADDR_P5 (RW) Address: 0Fh	58

3.14.2.17	TX_ADDR(RW) Address: 10h.....	58
3.14.2.18	RX_PW_P0 (RW) Address: 11h.....	59
3.14.2.19	RX_PW_P1 (RW) Address: 12h.....	60
3.14.2.20	RX_PW_P2 (RW) Address: 13h.....	60
3.14.2.21	RX_PW_P3 (RW) Address: 14h.....	61
3.14.2.22	RX_PW_P4 (RW) Address: 15h.....	61
3.14.2.23	RX_PW_P5 (RW) Address: 16h.....	62
3.14.2.24	FIFO_STATUS (RW) Address: 17h	62
3.14.2.25	DYNPD (RW) Address: 1Ch.....	63
3.14.2.26	FEATURE (RW) Address: 1Dh.....	63
3.14.2.27	SETUP_VALUE (RW) Address: 1Eh.....	64
3.14.2.28	PRE_GURD (RW) Address: 1Fh.....	65
3.14.3	Bank1	66
3.14.3.1	PLL_CTL0 (RW) Address: 01h	66
3.14.3.2	PLL_CTL1 (RW) Address: 02h	69
3.14.3.3	CAL_CTL (RW) Address: 03h.....	71
3.14.3.4	A_CNT_REG (RW) Address: 04h	73
3.14.3.5	B_CNT_REG (RW) Address: 05h	73
3.14.3.6	STATUS (RW) Address: 07h.....	73
3.14.3.7	STATE (RW) Address: 08h	74
3.14.3.8	CHAN (RW) Address: 09h	75
3.14.3.9	IF_FREQ (RW) Address: 0ah	76
3.14.3.10	AFC_COR (RW) Address: 0bh	76
3.14.3.11	FDEV (RW) Address: 0ch	77
3.14.3.12	DAC_RANGE (RW) Address: 0dh	77
3.14.3.13	DAC_IN (RW) Address: 0eh	78
3.14.3.14	CTUNING (RW) Address: 0fh	78
3.14.3.15	FTUNING (RW) Address: 10h.....	79
3.14.3.16	RX_CTRL (RW) Address: 11h	79
3.14.3.17	FAGC_CTRL (RW) Address: 12h	81
3.14.3.18	FAGC_CTRL_1 (RW) Address: 13h	81
3.14.3.19	DAC_CAL_LOW (RW) Address: 17h.....	82
3.14.3.20	DAC_CAL_HI (RW) Address: 18h	83
3.14.3.21	DOC_DACI (RW) Address: 1ah.....	83
3.14.3.22	DOC_DACQ (RW) Address: 1bh.....	83
3.14.3.23	AGC_CTRL (RW) Address: 1ch	84
3.14.3.24	AGC_GAIN (RW) Address: 1dh	85
3.14.3.25	RF_IVGEN (RW) Address: 1eh	86
3.14.3.26	TEST_PKDET (RW) Address: 1fh	87
4	MCU	90

8.3	32K OSC clock calibration	119
8.4	Reset Control	120
9	USB Configuration	121
9.1	Feature	121
9.2	Block diagram.....	122
9.3	MCU interface	122
9.4	Wakeup/suspend control.....	123
9.5	SFR register	123
9.5.1	USB Control register-USBCON	123
9.5.2	USBPCON registers —USBPCON	124
9.5.3	USBPCON registers —USBPCON1	124
9.6	USB Registers.....	125
9.6.1	Function address register– FADDR	125
9.6.2	Power management register-POWER.....	126
9.6.3	Interrupt register for Endpoint 0 plus IN Endpoints 1 to 7-INTRIN1	126
9.6.4	Interrupt register for IN Endpoints 8 to 15-INTRIN2.....	127
9.6.5	Interrupt register for OUT Endpoints 1 to 7-INTROUT1.....	127
9.6.6	Interrupt register for OUT Endpoints 8 to 15-INTROUT2.....	128
9.6.7	Interrupt register for common USB interrupts-INTRUSB	129
9.6.8	Interrupt enable register for INTRIN1-INTRIN1E.....	129
9.6.9	Interrupt enable register for INTRIN1-INTRIN2E.....	130
9.6.10	Interrupt enable register for INTROUT1-INTROUT1E.....	131
9.6.11	Interrupt enable register for INTROUT2-INTROUT2E.....	132
9.6.12	Interrupt enable register for INTRUSB-INTRUSBE.....	133
9.6.13	Frame number bits 0 to 7-FRAME1	134
9.6.14	Frame number bits 8 to 10-FRAME2	134
9.6.15	Index register for selecting the endpoint status and control registers-INDEX	135
9.6.16	Control Status register for Endpoint 0-CSR0	135
9.6.17	Maximum packet size for IN endpoint-INMAXP	136
9.6.18	Control Status register 1 for IN endpoint-INCSPR1.....	137
9.6.19	Control Status register 2 for IN endpoint-INCSPR2.....	137
9.6.20	Maximum packet size for OUT endpoint-OUTMAXP	138

9.6.21	Control Status register 1 for OUT endpoint-OUTCSR1.....	139
9.6.22	Control Status register 2 for OUT endpoint-OUTCSR2.....	139
9.6.23	Number of received bytes in Endpoint 0 FIFO-COUNT0.....	140
9.6.24	Number of bytes in OUT endpoint FIFO-OUTCOUNT1.....	141
9.6.25	Number of bytes in OUT endpoint FIFO-OUTCOUNT2.....	141
9.6.26	FIFOs for Endpoints 0 to 3-FIFOx	141
10	SPI	143

16.4.2	PWM frequency pre-scale factor register–PWMCON1	203
16.4.3	PWM control initial and active level register–PWMCRO, PWMCRI.....	203
16.4.4	PWM control the inactive level width registers–PWMDCO, PWMDC1, PWMDC2,PWMDC3,PWMDC4,PWMDC5	205

1 Introduction

The HS6206 is a member of the low-cost, high-performance family of intelligent 2.4 GHz RF transceivers with embedded microcontrollers. The HS6206 is optimized to provide a single chip solution for Ultra Low Power (ULP) wireless applications. The combination of processing power, memory, low power oscillators, real-time counter and a range of power saving modes provides an ideal platform for implementation of RF protocols. Benefits of using HS6206 include tighter protocol timing, security, lower power consumption and improved co-existence performance. For the application layer the HS6206 offers a rich set of peripherals including: SPI (master and slave), UART, PWM, USB, and so on.

1.1 Pad assignment

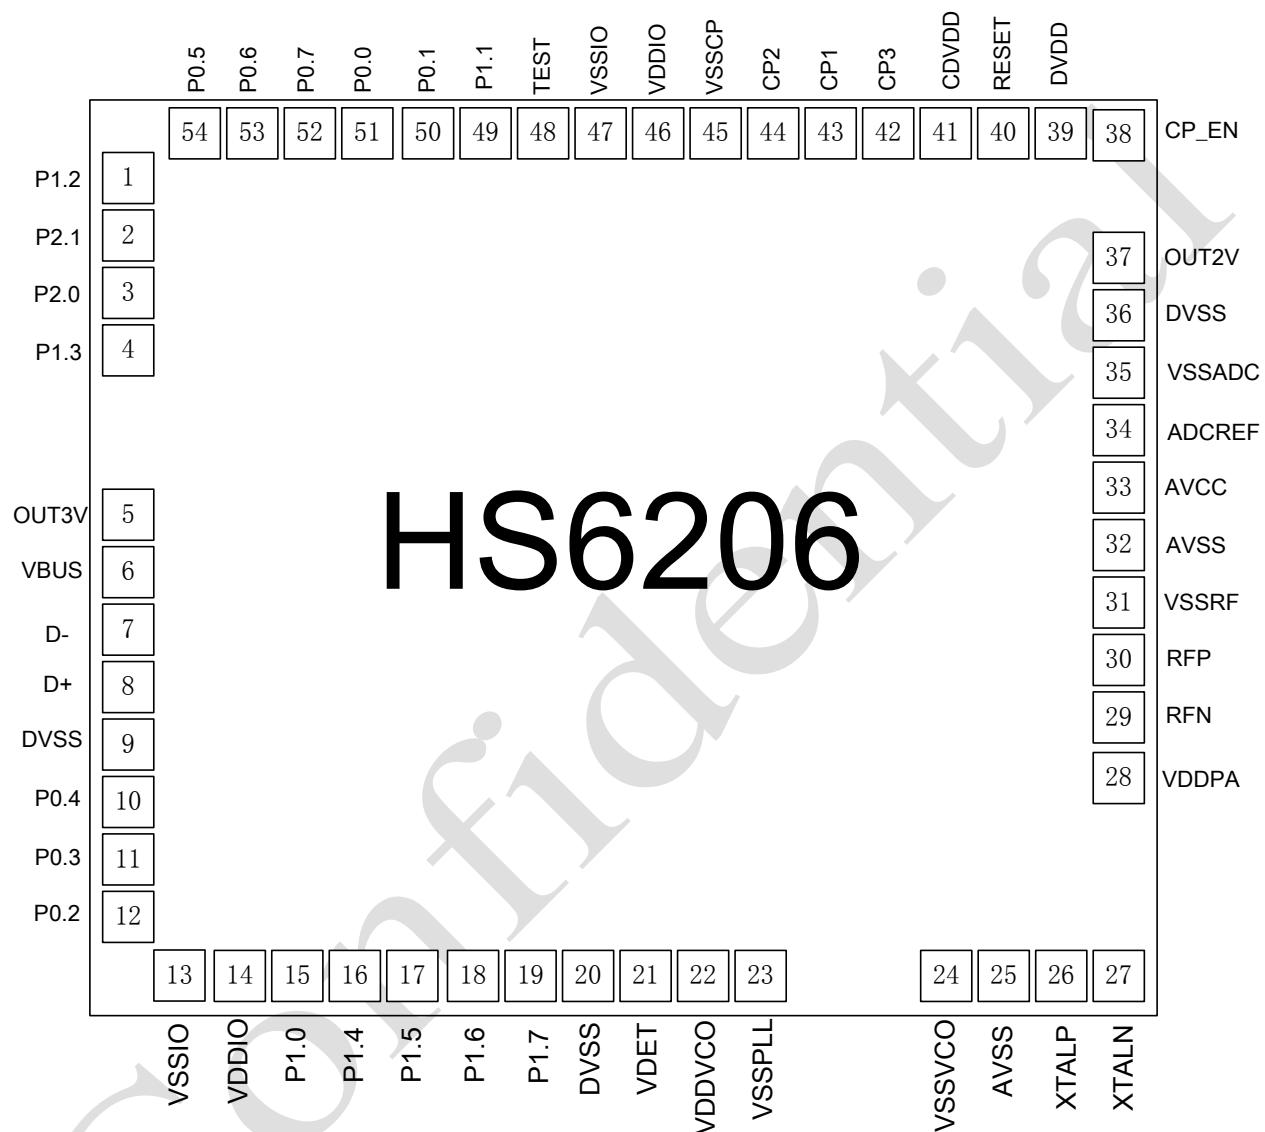

Figure1.1 HS6206pad assignment

1.2 Pad function

Table1.1 HS6206 pad function

Pin#	Name	Description
1	P1.2	General purpose IO
2	P2.1	General purpose IO
3	P2.0	General purpose IO
4	P1.3	General purpose IO
5	OUT3V	3.3V supply output for de-coupling, for USB dongle
6	VBUS	USB 5V power
7	D-	USB data-
8	D+	USB data+
9	DVSS	digital ground
10	P0.4	General purpose IO
11	P0.3	General purpose IO
12	P0.2	General purpose IO
13	VSSIO	IO ground
14	VDDIO	IO power
15	P1.0	General purpose IO
16	P1.4	General purpose IO
17	P1.5	General purpose IO
18	P1.6	General purpose IO
19	P1.7	General purpose IO
20	DVSS	Digital ground
21	VDET	Battery voltage detection
22	VDDVCO	VCO power
23	VSSPLL	PLL ground
24	VSSVCO	VCO ground
25	AVSS	Analog ground
26	XTALP	Crystal+
27	XTALN	Crystal-
28	VDDPA	PA power
29	RFN	RF-
30	RFP	RF+
31	VSSRF	RF ground
32	AVSS	Analog ground
33	AVCC	Analog power
34	ADCREF	ADC reference, connected to de-coupling capacitor
35	VSSADC	ADC ground

36	DVSS	digital ground
37	OUT2V	1.9V supply output for de-coupling, for low voltage sensor
38	CP_EN	Tie high: enable charge pump; tie low: disable charge pump
39	DVDD	Digital power
40	RESET	Reset for MCU, active low
41	CDVDD	Internal digital supply output for de-coupling
42	CP3	charge pump output for de-coupling
43	CP1	CP1 and CP2 connected to fly capacitor of charge pump
44	CP2	CP1 and CP2 connected to fly capacitor of charge pump
45	VSSCP	Charge pump ground
46	VDDIO	IO power
47	VSSIO	IO ground
48	TEST	Weak pull down in the PAD; 1 for OTP write & test mode; floating for normal work
49	P1.1	General purpose IO
50	P0.1	General purpose IO
51	P0.0	General purpose IO
52	P0.7	General purpose IO
53	P0.6	General purpose IO
54	P0.5	General purpose IO

Note: CP1, CP2, CP3 and CP_EN have different bonding and off-chip device for different applications:

- (1) If the power supply is higher than 3.0v, the internal charge pump is not needed, CP1 and CP2 can be floating, CP3 should be connected to power, CP_EN is bonded to ground;
- (2) If the power supply is lower than 3.0v, the internal charge pump is needed for OTP, 1uF capacitor should be put between CP1 and CP2, 10uF capacitor should be put between CP3 and ground, CP_EN is bonded to power;

If a unified off-chip circuit is needed for all applications, the way of (2) can be used.

1.3 Package

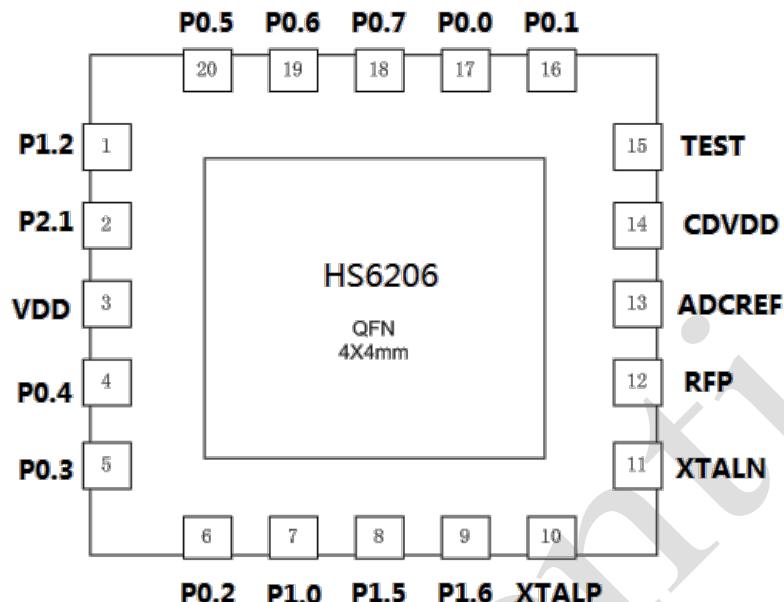

Figure1.2 HS6206 QFN20

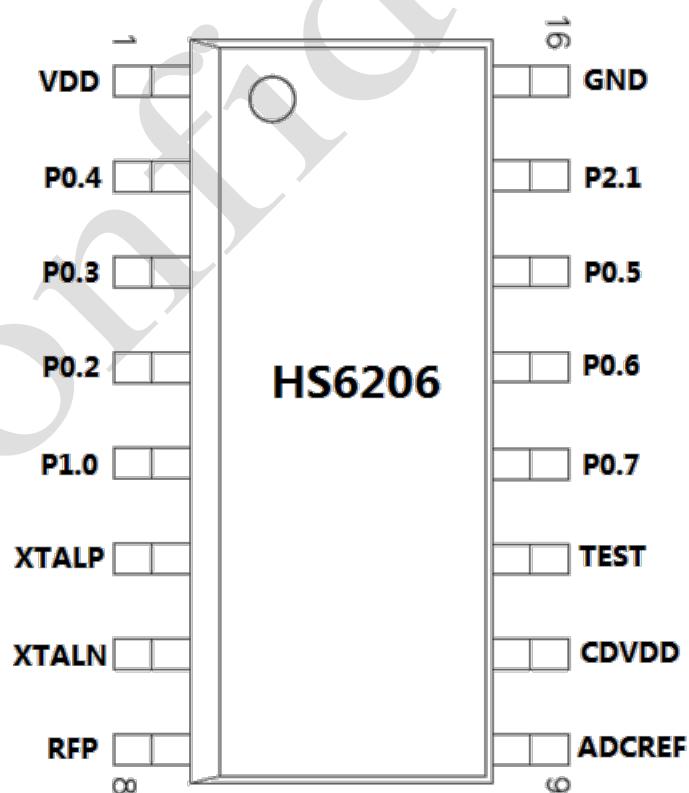

Figure1.3 HS6206 SOP16

2 Product overview

2.1 Features

Features of the HS6206 include:

- Fast 8-bit microcontroller:
 - Intel MCS 51 compliant instruction set
 - Reduced instruction cycle time, up to 12 times compared to legacy 8051
- Memory:
 - Program memory: 16 kB of OTP memory with security features
 - Internal RAM: 256Byte
 - User Data memory: 256 byte of on-chip RAM memory
- A number of on-chip hardware resources are available through programmable multi-purpose input/output pins:
 - 18 GPIO
 - SPI master
 - SPI slave
 - Full duplex serial port
 - 6PWMs
 - External interrupts
 - Timer inputs
- High performance 2.4 GHz RF transceiver
 - True single chip GFSK transceiver
 - Enhanced ShockBurst™ link layer support in HW:
 - ◆ Packet assembly/disassembly
 - ◆ Address and CRC computation
 - ◆ Auto ACK and retransmit
 - On the air data rate 500 kbps, 1 Mbps or 2 Mbps
 - 125 RF channels operation, with 79 (2.402 GHz –2.480 GHz) channels within 2.400–2.4835 GHz
 - Short switching time enable frequency hopping
- System reset and power supply monitoring:
 - On-chip power-on and brown-out reset
 - Watchdog timer reset
 - Reset from pin
 - Power-fail comparator with programmable threshold and interrupt to MCU
- On-chip timers:
 - Three 16-bit timers/counters operating at the system clock (sources from the 16 MHz on-chip oscillators)
 - Timer 0, Timer 1 are compatible to standard 8051
 - Timer 2 supports timer mode and compare/capture mode

- One 24-bit timer/counter operating at the low frequency clock (32kHz)
- On-chip oscillators:
 - 16 MHz crystal oscillator XOSC16M
 - 16 MHz RC-oscillator RCOSC16M
 - 32kHz RC-oscillator RCOSC32K
- Power management function:
 - Low power design supporting fully static stop/ standby
 - Programmable MCU clock frequency from 125 kHz to 16 MHz
 - On chip voltage regulators supporting low power mode
 - Watchdog and wakeup functionality running in low power mode

2.2 Blocks

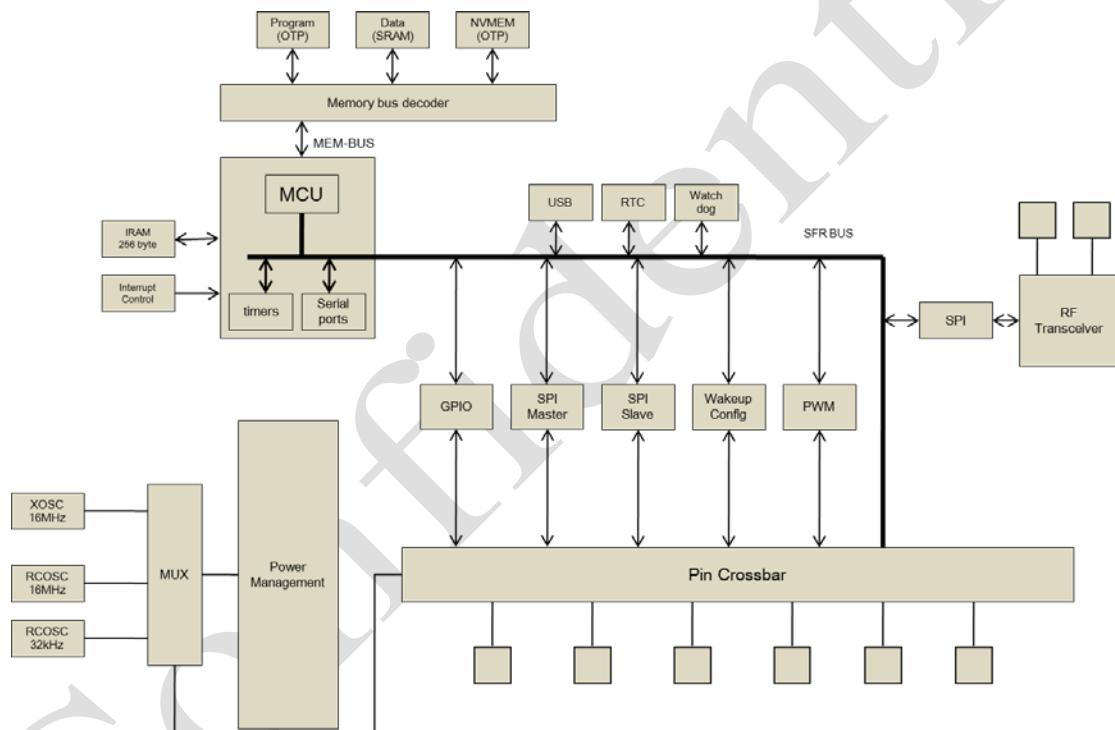

Figure2.1HS6206 block diagram

3 RF transceiver

The HS6206 uses the same 2.4 GHz GFSK RF transceiver with embedded protocol engine. The RF transceiver is designed for operation in the world wide ISM frequency band at 2.400–2.4835 GHz and is very well suited for ultra-low power wireless applications.

The RF transceiver module is configured and operated through the RF transceiver map. This register map is accessed by the MCU through a dedicated on-chip Serial Peripheral interface (SPI) and is available in all power modes of the RF transceiver module. The embedded protocol engine enables data packet communication and supports various modes from manual operation to advanced autonomous protocol operation. Data FIFOs in the RF transceiver module ensure a smooth data flow between the RF transceiver module and the HS6206MCU.

The rest of this chapter is written in the context of the RF transceiver module as the core and the rest of the HS6206 as external circuitry to this module.

3.1 Features

Features of the RF transceiver include:

- General
 - Worldwide 2.4 GHz ISM band operation
 - Common antenna interface in transmit and receive
 - GFSK modulation
 - 500 kbps, 1 Mbps and 2 Mbps on air data rate
- Transmitter
 - Programmable output power: 8, 5, 0, -6, -12 , -30dBm(8dBm@3V)
 - 18.5mA at 0dBm output power
- Receiver
 - Integrated channel filters
 - 19.5mA at 2 Mbps
 - -85dBm sensitivity at 2 Mbps
 - -88dBm sensitivity at 1 Mbps
 - -90dBm sensitivity at 500 kbps
- RF Synthesizer
 - Fully integrated synthesizer
 - 1 MHz frequency programming resolution
 - Accepts low cost $\pm 60\text{ppm}$ 16 MHz crystal
 - 1 MHz non-overlapping channel spacing at 1 Mbps
 - 2 MHz non-overlapping channel spacing at 2 Mbps
- Protocol Engine
 - 1 to 32 bytes dynamic payload length

- Automatic packet handling (assembly/disassembly)
- Automatic packet transaction handling (auto ACK, auto retransmit)
- 6 data pipe MultiSlave for 6:1 star networks

3.2 Block

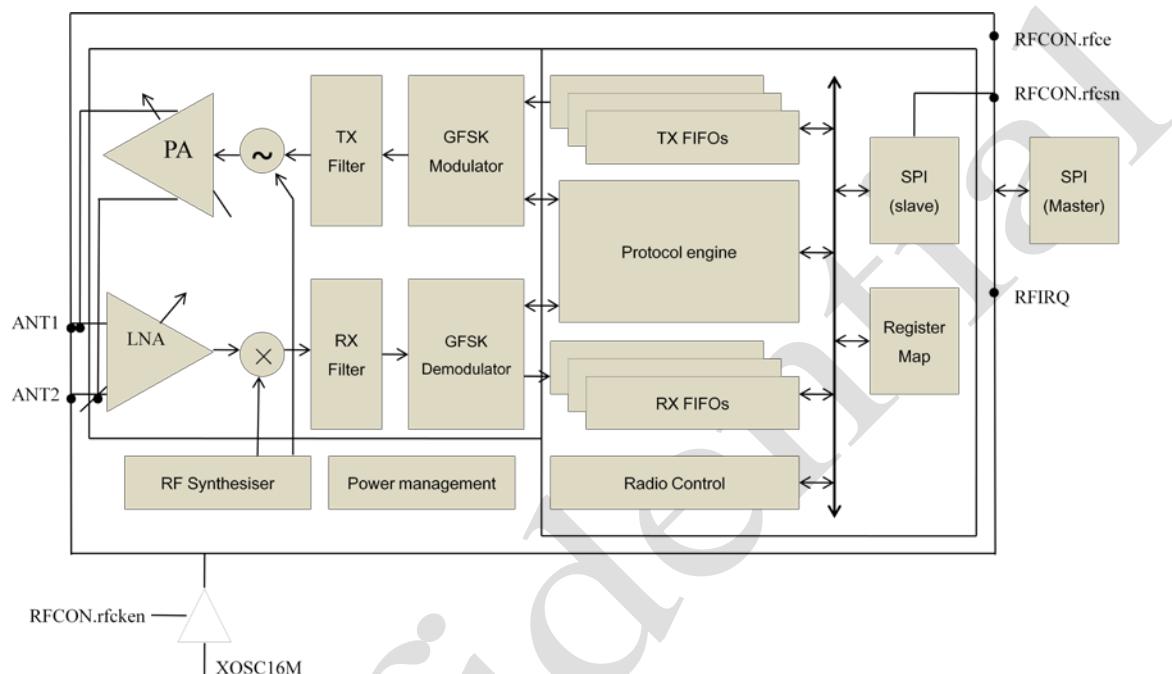

Fig.3.1 RF transceiver block diagram

3.3 Functional description

This section describes the different operating modes of the RF transceiver and the parameters used to control it.

The RF transceiver module has a built-in state machine that controls the transitions between the different operating modes. The state machine is controlled by SFR register RFCON and RF transceiver register CONFIG.

3.4 Operational Modes

The HS6206 has a built-in state machine that controls the transitions between the chip's operating modes. The state machine takes input from user defined register values and internal signals.

The state diagrams in Figure 3.2 shows the operating modes and how they function. There are three types of distinct states highlighted in the state diagram:

- Recommended operating mode: is a recommended state used during normal operation.
- Possible operating mode: is a possible operating state, but is not used during normal operation.
- Transition state: is a time limited state used during start up of the oscillator and settling of the PLL.

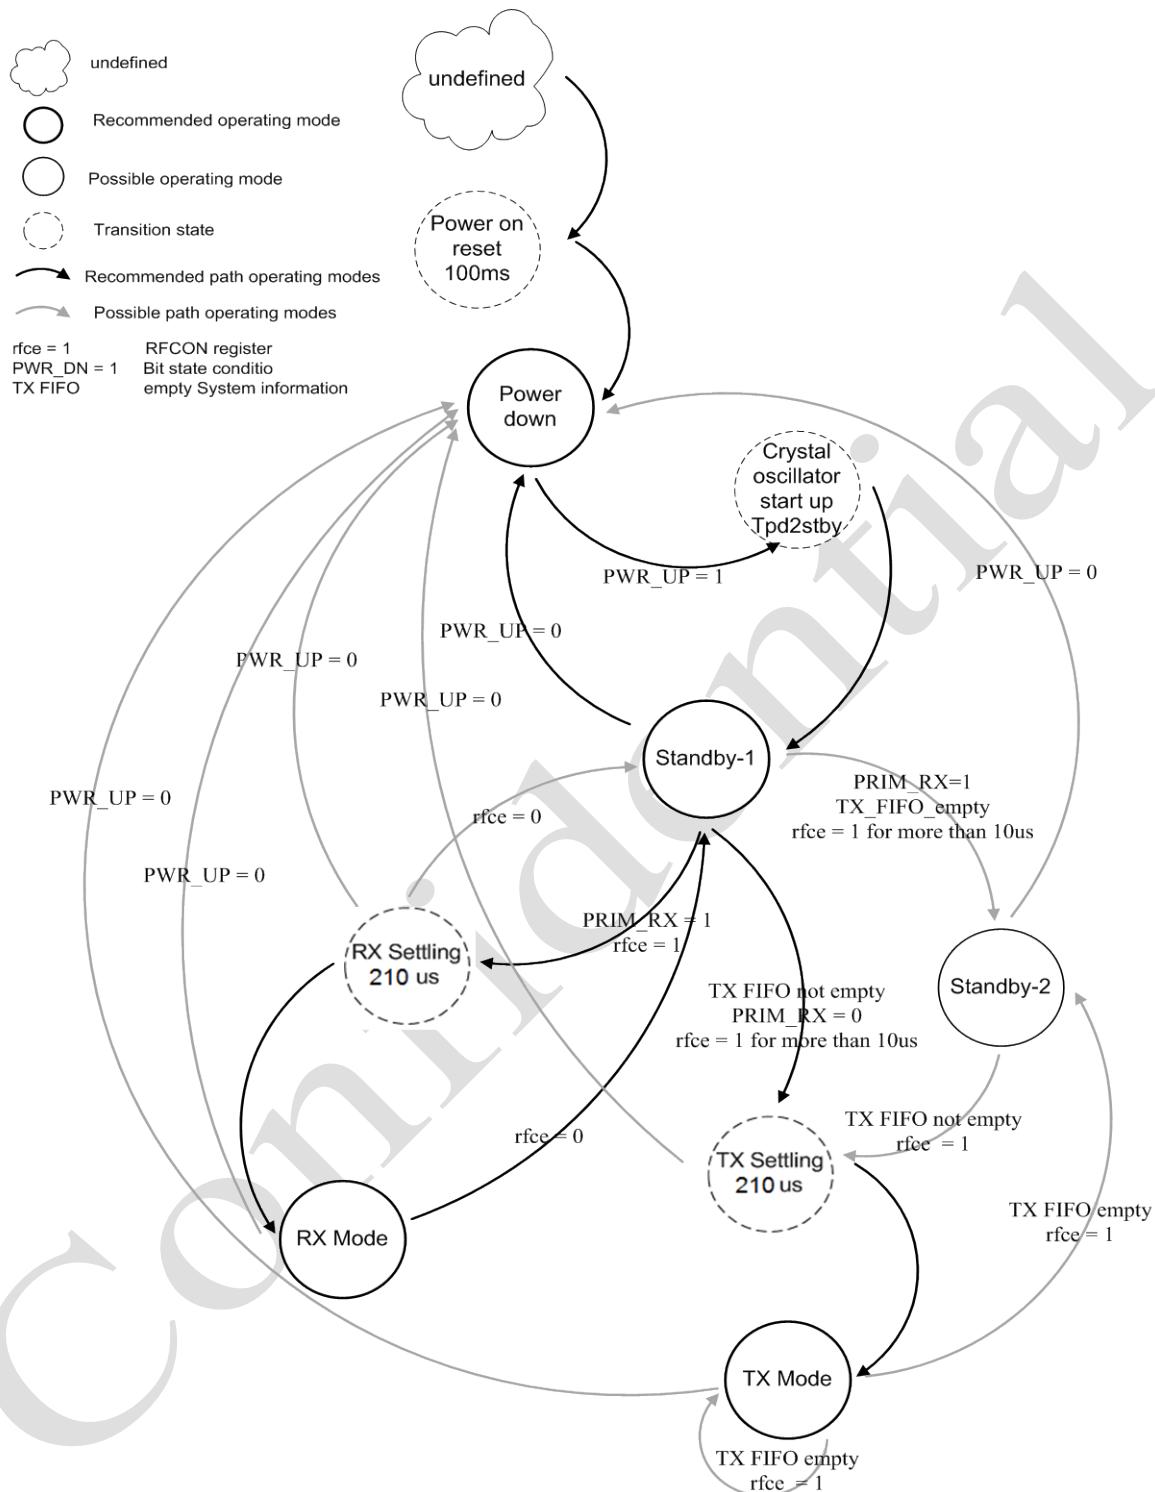

Fig. 3.2 Radio control state diagram

Note: TX/RX settling time can be set to 140us minimum

3.4.1 PowerDown Mode

In power down mode, the HS6206 is disabled using minimal current consumption. All register values available are maintained and the SPI is kept active, enabling change of configuration and the uploading/down-loading of data registers. For starting up times see Table3.2.Power down mode is entered when the chip is in deep sleep or register retention mode (Details are described in chapter 7).

3.4.2 Standby Modes

3.4.2.1 Standby-I mode

When the chip is power up or wake up from deep sleep or register retention mode, the device enters standby-I mode. Standby-I mode is used to minimize average current consumption while maintaining short start up times. In this mode only part of the crystal oscillator is active. Change to active modes only happens if CE is set high and when CE is set low, the HS6206 returns to standby-I mode from both the TX and RX modes.

3.4.2.2 Standby-II mode

In standby-II mode extra clock buffers are active and more current is used compared to standby-I mode. The HS6206 enters standby-II mode if CE is held high on a PTX device with an empty TX FIFO. If a new packet is uploaded to the TX FIFO, the PLL immediately starts and the packet is transmitted after the normal PLL settling delay (default 210 μ s, can be set to 140us). Register values are maintained and the SPI can be activated during both standby modes.

Notice: From Standby-I mode to standby-II mode CE more than 20us

3.4.3 RX mode

The RX mode is an active mode where the HS6206 radio is used as a receiver. To enter this mode, the chip must have PRIM_RX bit and the CE pin set high.

In RX mode the receiver demodulates the signals from the RF channel, constantly presenting the demodulated data to the baseband protocol engine. The baseband protocol engine constantly searches for a valid packet. If a valid packet is found (by a matching address and a valid CRC) the payload of the packet is presented in a vacant slot in the RX FIFOs. If the RX FIFOs are full, the received packet is discarded.

The chip remains in RX mode until the MCU configures it to standby-I mode or power down mode. However, if the automatic protocol features in the baseband protocol engine are enabled, the chip can enter other modes in order to execute the protocol.

In RX mode a Received Power Detector (RPD) signal is available. The RPD register is a signed number which corresponds to different level of received power in dBm. The highest bit of RPD is sign bit. The range of the received power is -100 ~ +10dBm. The RPD has about +/-5dBm deviation from the real level.

3.4.4 TX mode

The TX mode is an active mode for transmitting packets. To enter this mode, the chip must have the PWR_UP bit set high, PRIM_RX bit set low, a payload in the TX FIFO and a high pulse on the CE for more than 20μs.

The HS6206 stays in TX mode until it finishes transmitting a packet. If CE = 0, the chip returns to standby-I mode. If CE = 1, the status of the TX FIFO determines the next action. If the TX FIFO is not empty the HS6206 remains in TX mode and transmits the next packet. If the TX FIFO is empty the chip goes into standby-II mode.

3.4.5 Operational modes configuration

The following (table 1) describes how to configure the operational modes:

Mode	PWR_UP register	PRIM_RX register	CE input pin	FIFO state
RX mode	1	1	1	-
TX mode	1	0	1	Data TX FIFO. Will empty all level in TX FIFOs ^a
TX mode	1	0	Minimum 20us high pulse	Data TX FIFO. Will empty one level in TX FIFOs ^b
Standby-2	1	0	1	TX FIFO empty
Standby-1	1	-	0	No ongoing packet transmission
Power Down	0	-	-	-

Table 3.1 the HS6206 main modes

- a. If CE is held high all TX FIFOs are emptied and all necessary ACK and possible retransmits are carried out. The transmission continues as long as the TX FIFO is refilled. If the TX FIFO is empty when the CE is still high, the chip enters standby-II mode. In this mode the transmission of a packet is started as soon as the CSN is set high after an upload (UL) of a packet to TX FIFO.
- b. This operating mode pulses the CE high for at least 20μs. This allows one packet to be transmitted. This is the normal operating mode. After the packet is transmitted, the chip enters standby-1 mode.

3.4.6 Timing Information

The timing information in this section relates to the transitions between modes and the timing for the CE pin. The transition from TX mode to RX mode or vice versa is the same as the transition from the standby modes to TX mode or RX mode (max. 210μs), as described in Table 3.2.

Name	The chip	Notes	Max.	Min.	Comments
T _{pd2stby}	Power down → Standby mode		150us		With external clock
		a	1.5ms		External crystal, Ls < 30mH

			3ms		External crystal, Ls< 60mH
			4.5ms		External crystal, Ls< 90mH
T _{stby2a}	Standby mode → TX/RX mode		210us		
T _{hce}	Minimum CE high			20us	
T _{pece2csn}	Delay from CE positive edge to CSN low			4us	

a. See crystal specifications.

Tab. 3.2 operational timing of the HS6206 chip

HS6206 to go from power down mode to TX or RX mode it must first pass through stand-by mode. There must be a delay of Tpd2stby (see Table 3.2.) after the chip leaves power down mode before the RFCON.rfce is set high.

Note: If VDD is turned off the register value is lost and you must configure chip before entering the TX or RX modes.

3.4.7 Air data rate

The air data rate is the modulated signaling rate the chip uses when transmitting and receiving data. It can be 500kbps, 1Mbps or 2Mbps. Using lower air data rate gives better receiver sensitivity than higher air data rate. But, high air data rate gives lower average current consumption and reduced probability of on-air collisions. The air data rate is set by the RF_DR bit in the RF_SETUP register. A transmitter and a receiver must be programmed with the same air data rate to communicate with each other.

3.4.8 RF channel frequency

The RF channel frequency determines the center of the channel used by the chip. The channel occupies a bandwidth of less than 1MHz at 250kbps and 1Mbps and a bandwidth of less than 2MHz at 2Mbps. The chip can operate on frequencies from 2.400GHz to 2.525GHz. The programming resolution of the RF channel frequency setting is 1MHz.

At 2Mbps the channel occupies a bandwidth wider than the resolution of the RF channel frequency setting. To ensure non-overlapping channels in 2Mbps mode, the channel spacing must be 2MHz or more. At 1Mbps the channel bandwidth is the same as or lower than the resolution of the RF frequency.

The RF channel frequency is set by the RF_CH register according to the following formula:

$$F0 = 2400 + RF_CH \text{ [MHz]}$$

You must program a transmitter and a receiver with the same RF channel frequency to communicate with each other.

3.4.9 Received Power Detector measurements

Received Power Detector (RPD), located in register 09, is a signed number which corresponds to different level of received power in dBm. The highest bit of RPD is sign bit. The range of the received power is -100 ~ +10dBm.

The RPD can be read out at any time while the chip is in received mode. This offers a snapshot of the current received power level in the channel. The status of RPD is correct when RX mode is enabled and after a wait time of $T_{\text{stby2a}} + T_{\text{delay_AGC}} = 210\text{us} + 20\text{us}$. The RX gain varies over temperature which means that the RPD value also varies over temperature.

3.4.10 PA control

The PA (Power Amplifier) control is used to set the output power from the chip power amplifier. In TX mode PA control has four programmable steps, see Table 3.3.

The PA control is set by the RF_PWR bits in the RF_SETUP register.

SPI RF-SETUP (RF_PWR)	RF output power	DC current consumption
1111	8dBm	40mA
1000	5dBm	25mA
0011	0dBm	18.5mA
0001	-6dBm	16mA

Conditions: VDD = 3.0V, VSS = 0V, TA = 27°C

Note: DC current above is TX current, including all TX block

Tab.3.3 RF output power setting for the HS6206

3.4.11 RX/TX control

The RX/TX control is set by PRIM_RX bit in the CONFIG register and sets the HS6206 chip in transmit/receive mode.

3.5 Protocol Engine

Protocol engine is a packet based data link layer that features automatic packet assembly and timing, automatic acknowledgement and retransmissions of packets. Protocol engine enables the implementation of ultralow power and high performance communication. The Protocol engine features enable significant improvements of power efficiency for bi-directional and uni-directional systems, without adding complexity on the host controller side.

3.5.1 Features

The main features of Protocol engine are:

- 1 to 32 bytes dynamic payload length
- Automatic packet handling
- Automatic packet transaction handling
 - Auto Acknowledgement with payload

- Auto retransmit
- 6 data pipe for 1:6 star networks

3.6 Protocol engine overview

Protocol engine uses self-defined protocol for automatic packet handling and timing. During transmit, Protocol engine assembles the packet and clocks the bits in the data packet for transmission. During receive, Protocol engine constantly searches for a valid address in the demodulated signal. When Protocol engine finds a valid address, it processes the rest of the packet and validates it by CRC. If the packet is valid the payload is moved into a vacant slot in the RX FIFOs. All high speed bit handling and timing is controlled by protocol engine.

Protocol engine features automatic packet transaction handling for the easy implementation of a reliable bi-directional data link. A protocol engine packet transaction is a packet exchange between two transceivers, with one transceiver acting as the Primary Receiver (PRX) and the other transceiver acting as the Primary Transmitter (PTX). A protocol engine packet transaction is always initiated by a packet transmission from the PTX, the transaction is complete when the PTX has received an acknowledgment packet (ACK packet) from the PRX. The PRX can attach user data to the ACK packet enabling a bi-directional data link.

The automatic packet transaction handling works as follows:

1. You begin the transaction by transmitting a data packet from the PTX to the PRX. Protocol engine automatically sets the PTX in receive mode to wait for the ACK packet.
2. If the packet is received by the PRX, Protocol engine automatically assembles and transmits an acknowledgment packet (ACK packet) to the PTX before returning to receive mode.
3. If the PTX does not receive the ACK packet immediately, Protocol engine automatically retransmits the original data packet after a programmable delay and sets the PTX in receive mode to wait for the ACK packet.

In Protocol engine it is possible to configure parameters such as the maximum number of retransmits and the delay from one transmission to the next retransmission. All automatic handling is done without the involvement of the MCU.

3.7 Protocol engine packet format

The format of the Protocol engine packet is described in this section. The Protocol engine packet contains a preamble field, address field, packet control field, payload field and a CRC field. Figure3.3 shows the packet format with MSB to the left.

Preamble 1 byte	Address 4-5 byte	2byte guard	Packet control field 9 bit	Payload 0-32 bytes	CRC 1-2 bytes
-----------------	------------------	-------------	----------------------------	--------------------	---------------

Figure3.3 A Protocol engine packet with payload (0-32 bytes)

3.7.1 Preamble

The preamble is a bit sequence used to synchronize the receivers demodulator to the incoming bit stream. The preamble is one byte long and is either 01010101 or 10101010. If the first bit in the address is 1 the preamble is automatically set to 10101010 and if the first bit is 0 the preamble is automatically set to 01010101. This is done to ensure there are enough transitions in the preamble to

stabilize the receiver.

3.7.2 Address

This is the address for the receiver. An address ensures that the packet is detected and received by the correct receiver, preventing accidental cross talk between multiple HS6206 systems. You can configure the address field width in the AW register to be 5 bytes or 4 bytes address.

3.7.3 Guard

Figure 3.3 shows the format of the 2bytesguard packet has better synchronous characteristics.

3.7.4 Packet Control Field (PCF)

Figure 3.4 shows the format of the 9 bit packet control field, MSB to the left.

Payload length 6bit	PID 2bit	NO_ACK 1bit
---------------------	----------	-------------

Figure 3.4 Packet control field (PCF)

The packet control field contains a 6 bit payload length field, a 2 bit PID (Packet Identity) field and a 1 bit NO_ACK flag.

Payload length

This 6 bit field specifies the length of the payload in bytes. The length of the payload can be from 0 to 32 bytes.

Coding: 000000 = 0 byte (only used in empty ACK packets. The 0 length packet also need to be read out use R_RX_PAYLOAD with no data following) 100000 = 32 byte, 100001 = Don't care

This field is only used if the Dynamic Payload Length function is enabled.

PID (Packet identification)

The 2 bit PID field is used to detect if the received packet is new or retransmitted. PID prevents the PRX operation from presenting the same payload more than once to the MCU. The PID field is incremented at the TX side for each new packet received through the SPI. The PID and CRC field are used by the PRX operation to determine if a packet is retransmitted or new. When several data packets are lost on the link, the PID fields may become equal to the last received PID. If a packet has the same PID as the previous packet, the RF transceiver compares the CRC sums from both packets. If the CRC sums are also equal, the last received packet is considered a copy of the previously received packet and discarded.

No Acknowledgment flag (NO_ACK)

The Selective Auto Acknowledgement feature controls the NO_ACK flag.

This flag is only used when the auto acknowledgement feature is used. Setting the flag high, tells the receiver that the packet is not to be auto acknowledged.

On the PTX you can set the NO_ACK flag bit in the Packet Control Field with this command:

W_TX_PAYLOAD_NOACK

However, the function must first be enabled in the FEATURE register by setting the EN_DYN_ACK bit. When you use this option, the PTX goes directly to standby-I mode after transmitting the packet. The PRX does not transmit an ACK packet when it receives the packet.

3.7.5 Payload

The payload is the user defined content of the packet. It can be 0 to 32 bytes wide and is transmitted on-air when it is uploaded to the device.

Protocol engine provides two alternatives for handling payload lengths; static and dynamic.

The default is static payload length. With static payload length all packets between a transmitter and a receiver have the same length. Static payload length is set by the RX_PW_Px registers on the receiver side. The payload length on the transmitter side is set by the number of bytes clocked into the TX_FIFO and must equal the value in the RX_PW_Px register on the receiver side.

Dynamic Payload Length (DPL) is an alternative to static payload length. DPL enables the transmitter to send packets with variable payload length to the receiver. This means that for a system with different payload lengths it is not necessary to scale the packet length to the longest payload.

With the DPL feature the HS6206 can decode the payload length of the received packet automatically instead of using the RX_PW_Px registers. The MCU can read the length of the received payload by using the R_RX_PL_WID command.

Note: Always check if the packet width reported is 32 bytes or shorter when using the R_RX_PL_WID command. If its width is longer than 32 bytes then the packet contains errors and must be discarded. Discard the packet by using the Flush_RX command.

In order to enable DPL the EN_DPL bit in the FEATURE register must be enabled. In RX mode the DYNPD register must be set. A PTX that transmits to a PRX with DPL enabled must have the DPL_P0 bit in DYNPD set.

3.7.6 CRC (Cyclic Redundancy Check)

The CRC is the error detection mechanism in the packet. It may either be 1 or 2 bytes and is calculated over the address, Packet Control Field and Payload.

HS6206

The polynomial for 1 byte CRC is $X^8 + X^2 + X + 1$. Initial value 0Xff.

The polynomial for 2 byte CRC is $X^{16} + X^{12} + X^5 + 1$. Initial value 0Xffff.

The number of bytes in the CRC is set by the CRC0 bit in the CONFIG register. No packet is accepted by protocol engine if the CRC fails.

3.7.7 Automatic packet assembly

The automatic packet assembly assembles the preamble, address, packet control field, payload and CRC to make a complete packet before it is transmitted.

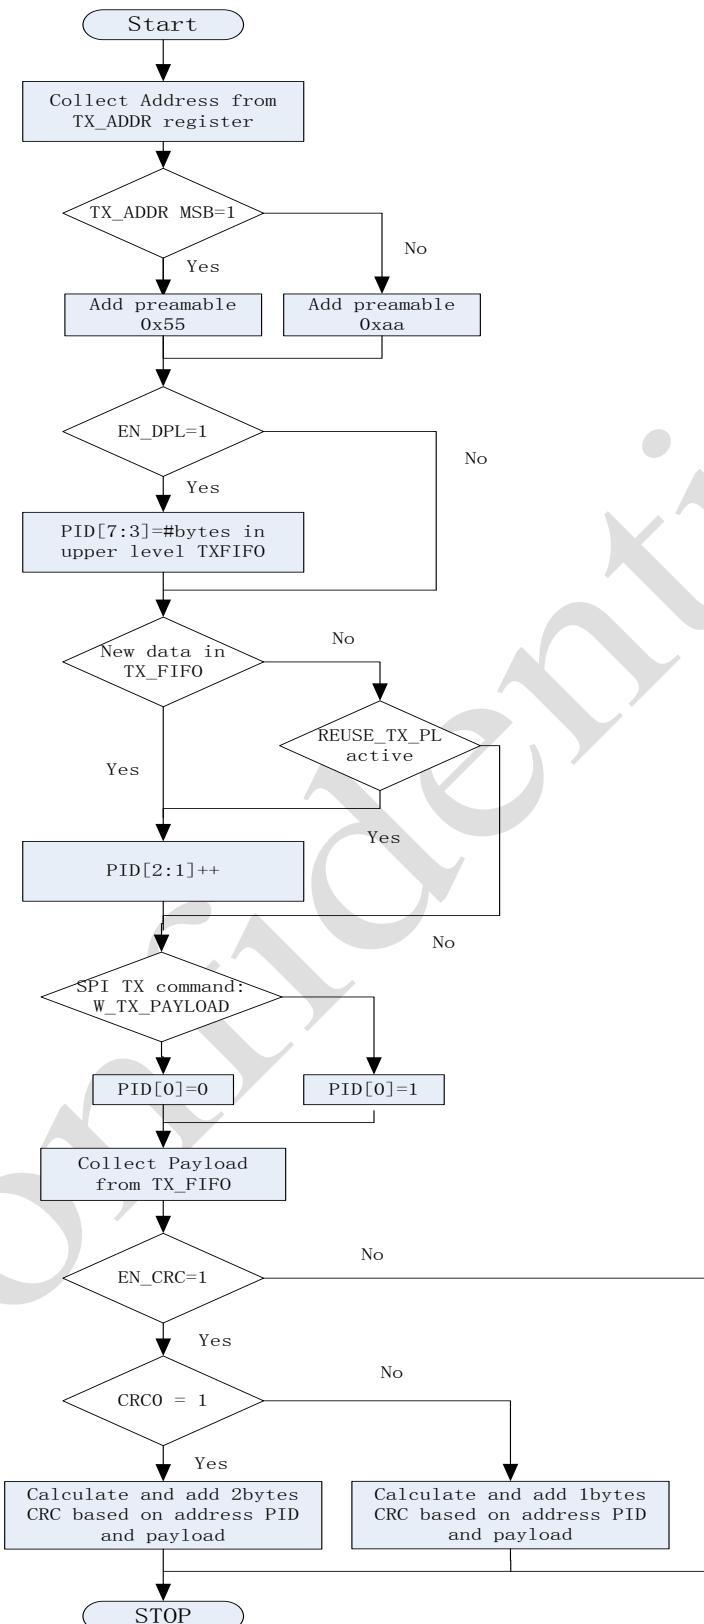

Figure 3.5 Automatic packetassembly

3.7.8 Automatic packet disassembly

After the packet is validated, Protocol engine disassembles the packet and loads the payload into the RX FIFO, and asserts the RX_DR IRQ.

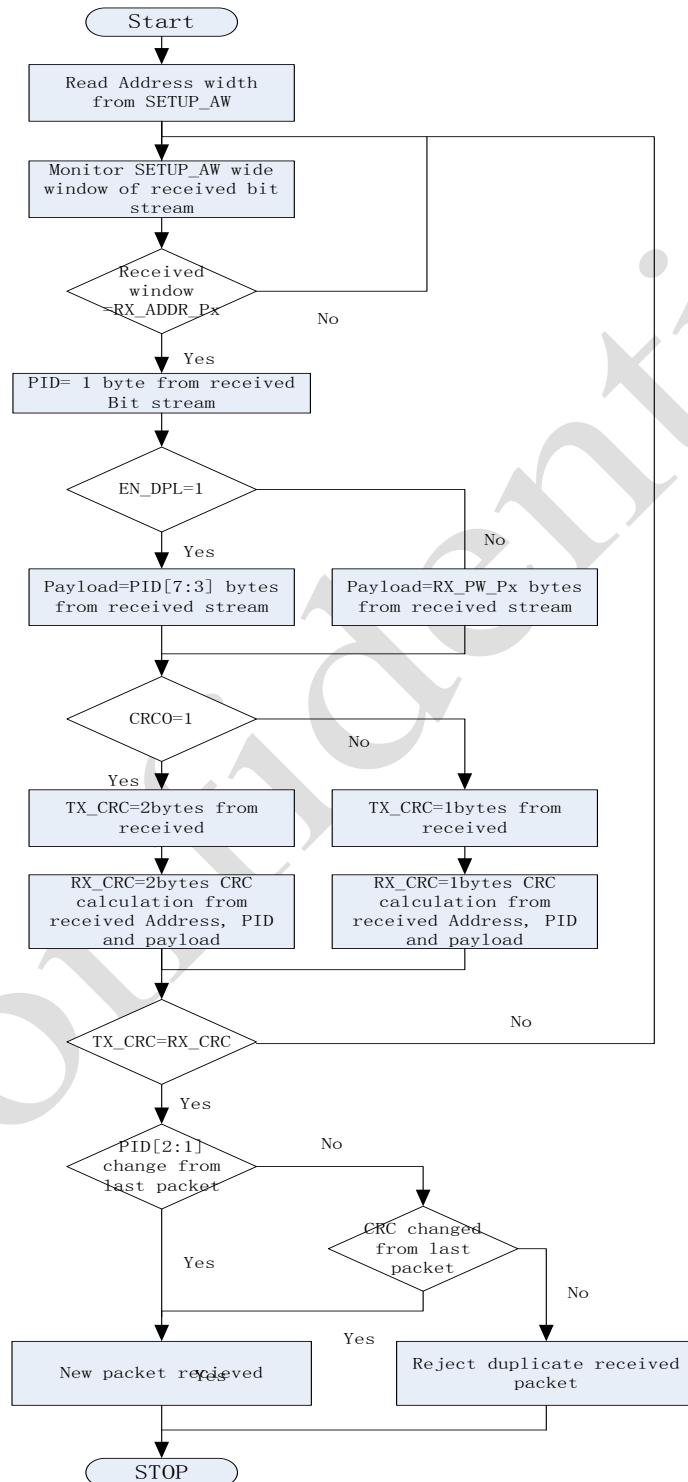

Figure 3.6Automatic packet disassembly

3.8 Automatic packet transaction handling

Protocol engine features two functions for automatic packet transaction handling; auto acknowledgement and auto re-transmit.

3.8.1 Auto Acknowledgement

Auto Acknowledgment is a function that automatically transmits an ACK packet to the PTX after it has received and validated a packet. The Auto Acknowledgement function reduces the load of the system MCU and reduces average current consumption. The Auto Acknowledgement feature is enabled by setting the EN_AA register.

Note: If the received packet has the NO_ACK flag set, auto acknowledgement is not executed.

An ACK packet can contain an optional payload from PRX to PTX. In order to use this feature, the Dynamic Payload Length (DPL) feature must be enabled. The MCU on the PRX side has to upload the payload by clocking it into the TX FIFO by using the W_ACK_PAYLOAD command. The payload is pending in the TX FIFO (PRX) until a new packet is received from the PTX. The RF transceiver can have three ACK packet payloads pending in the TX FIFO (PRX) at the same time.

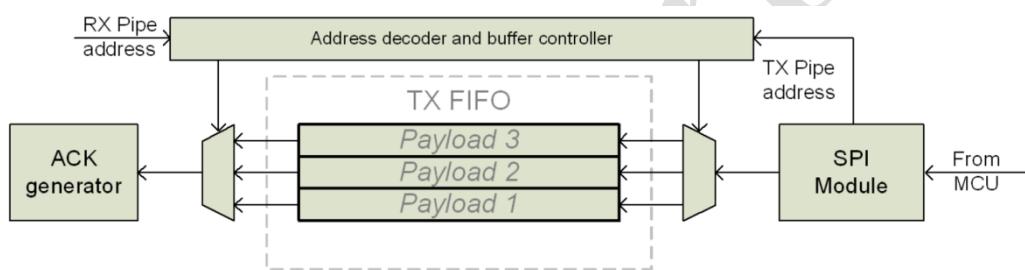

Fig. 3.7 TX FIFO (PRX) with pending payloads

Figure 3.7 shows how the TX FIFO (PRX) is operated when handling pending ACK packet payloads. From the MCU the payload is clocked in with the W_ACK_PAYLOAD command. The address decoder and buffer controller ensure that the payload is stored in a vacant slot in the TX FIFO (PRX). When a packet is received, the address decoder and buffer controller are notified with the PTX address. This ensures that the right payload is presented to the ACK generator.

If the TX FIFO (PRX) contains more than one payload to a PTX, payloads are handled using the first in–first out principle. The TX FIFO (PRX) is blocked if all pending payloads are addressed to a PTX where the link is lost. In this case, the MCU can flush the TX FIFO (PRX) by using the FLUSH_TX command.

In order to enable Auto Acknowledgement with payload the EN_ACK_PAY bit in the FEATURE register must be set.

3.8.2 Auto Retransmission (ART)

The auto retransmission is a function that retransmits a packet if an ACK packet is not received. It is used in an Auto Acknowledgement system on the PTX. When a packet is not acknowledged, you can set the number of times it is allowed to retransmit by setting the ARC bits in the SETUP_RETR register. PTX enters RX mode and waits a time period for an ACK packet each time a

packet is transmitted. The amount of time the PTX is in RX mode is based on the following conditions:

- Auto Retransmit Delay (ARD) has elapsed.
- No address match within 256μs.
- After received packet (CRC correct or not) if address match within 256μs.

The RF transceiver asserts the TX_DS IRQ when the ACK packet is received.

The RF transceiver enters standby-I mode if there is no more un-transmitted data in the TX FIFO and the CE pin is low. If the ACK packet is not received, the RF transceiver goes back to TX mode after a delay defined by ARD and retransmits the data. This continues until acknowledgment is received, or the maximum number of retransmits is reached.

Two packet loss counters are incremented each time a packet is lost, ARC_CNT and PLOS_CNT in the OBSERVE_TX register. The ARC_CNT counts the number of retransmissions for the current transaction. You reset ARC_CNT by initiating a new transaction. The PLOS_CNT counts the total number of retransmissions since the last channel change. You reset PLOS_CNT by writing to the RF_CH register. It is possible to use the information in the OBSERVE_TX register to make an overall assessment of the channel quality.

The ARD defines the time from the end of a transmitted packet to when a retransmit starts on the PTX. ARD is set in SETUP_RETR register in steps of 256μs. A retransmit is made if no ACK packet is received by the PTX.

There is a restriction on the length of ARD when using ACK packets with payload. The ARD time must never be shorter than the sum of the startup time and the time on-air for the ACK packet.

- For 2 Mbps data rate and 5-byte address; 15 byte is maximum ACK packet payload length for ARD=256μs (reset value).
- For 1 Mbps data rate and 5-byte address; 5 byte is maximum ACK packet payload length for ARD=256μs (reset value).

ARD=512μs is long enough for any ACK payload length in 1 or 2 Mbps mode.

- For 500kbps data rate and 5-byte address the following values apply:

ARD	ACK packet size (in byte)
1536us	All ACK payload sizes
1280us	<=24
1024us	<=16
768us	<=8
512us	Empty ACK with no payload

Table 3.4 Maximum ACK payload length for different retransmit delays

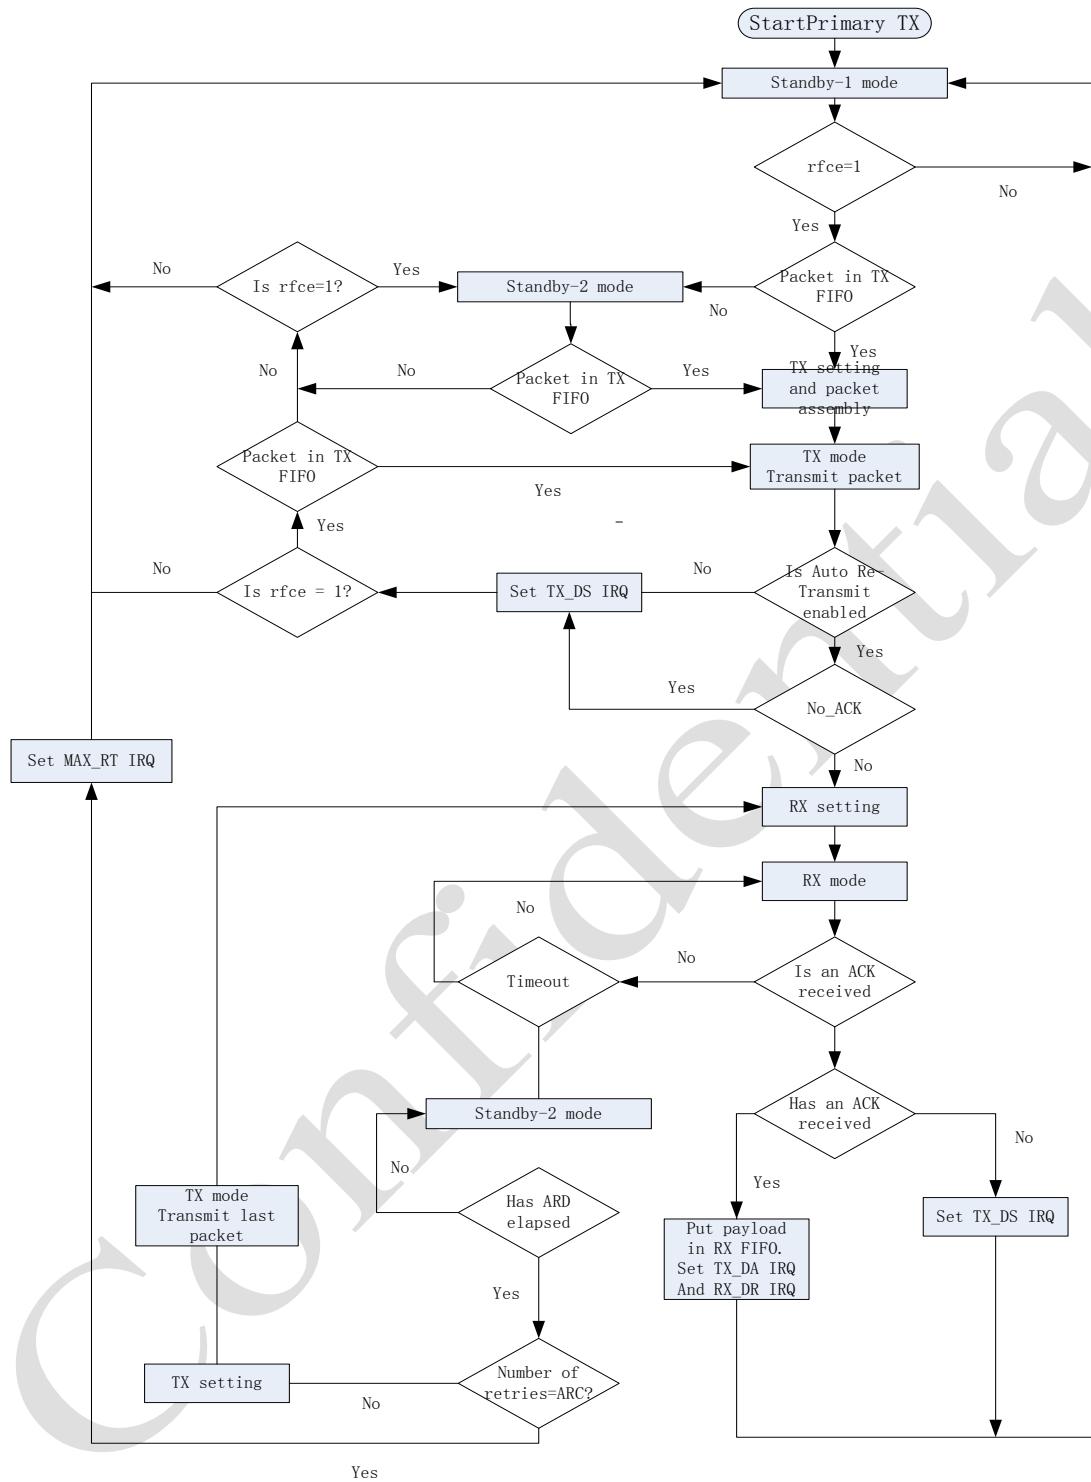

As an alternative to Auto Retransmit it is possible to manually set the RF transceiver to retransmit a packet a number of times. This is done by the REUSE_TX_PL command. The MCU must initiate each transmission of the packet with a pulse on the CE pin when this command is used.

3.9 Protocol engine flowcharts

This section contains flowcharts outlining PTX and PRX operation in Protocol engine.

3.9.1 PTX operation

The flowchart in Figure 3.8 outlines how a RF transceiver configured as a PTX behaves after entering standby-I mode.

Note: Protocol engine operation is outlined with a dashed square.

Figure 3.8 PTX operations in Protocol engine

Activate PTX mode by setting the rfce in the RFCON register high. If there is a packet present in the TX FIFO the RF transceiver enters TX mode and transmits the packet. If Auto Retransmit is enabled, the state machine checks if the NO_ACK flag is set. If it is not set, the RF transceiver enters RX mode to receive an ACK packet. If the received ACK packet is empty, only the TX_DS IRQ is

asserted. If the ACK packet contains a payload, both TX_DS IRQ and RX_DR IRQ are asserted simultaneously before the RF transceiver returns to standby-I mode.

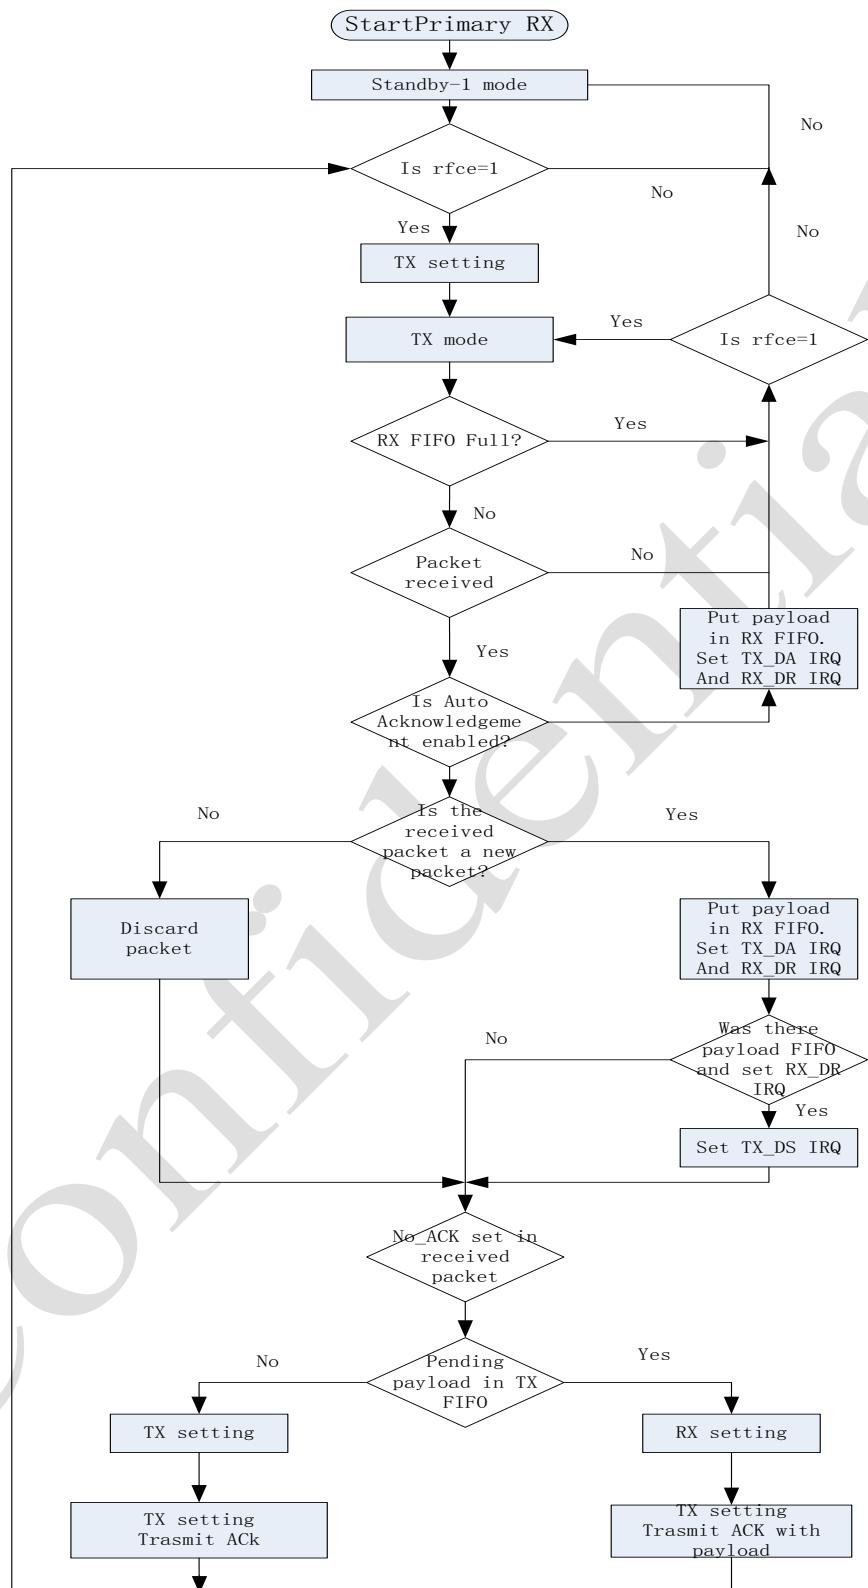

If the ACK packet is not received before timeout occurs, the RF transceiver returns to standby-II mode. It stays in standby-II mode until the ARD has elapsed. If the number of retransmits has not reached the ARC, the RF transceiver enters TX mode and transmits the last packet once more.

While executing the Auto Retransmit feature, the number of retransmits can reach the maximum number defined in ARC. If this happens, the RF transceiver asserts the MAX_RT IRQ and returns to standby-I mode.

If the rfce bit in the RFCON register is high and the TX FIFO is empty, the RF transceiver enters Standby-II mode.

3.9.2 PRX operation

The flowchart in Figure 3.9 outlines how a RF transceiver configured as a PRX behaves after entering standby-I mode.

Note:Protocol engine operation is outlined with a dashed square.

Figure3.9 PRX operations in Protocol engine

Activate PRX mode by setting the rfce bit in the RFCON register high. The RF transceiver enters RX mode and starts searching for packets. If a packet is received and Auto Acknowledgement is enabled, the RF transceiver decides if the packet is new or a copy of a previously received packet. If the packet is new payload is made available in the RX FIFO and the RX_DR IRQ is asserted. If the last received packet from the transmitter is acknowledged with an ACK packet with payload, the TX_DS IRQ indicates that the PTX received the ACK packet with payload. If the No_ACK flag is not set in the received packet, the PRX enters TX mode. If there is a pending payload in the TX FIFO it is attached to the ACK packet. After the ACK packet is transmitted, the RF transceiver returns to RX mode.

A copy of a previously received packet might be received if the ACK packet is lost. In this case, the PRX discards the received packet and transmits an ACK packet before it returns to RX mode.

3.10 MultiSlave

MultiSlave is a feature used in RX mode that contains a set of six parallel data pipes with unique addresses. A data pipe is a logical channel in the physical RF channel. Each data pipe has its own physical address (data pipe address) decoding in the RF transceiver.

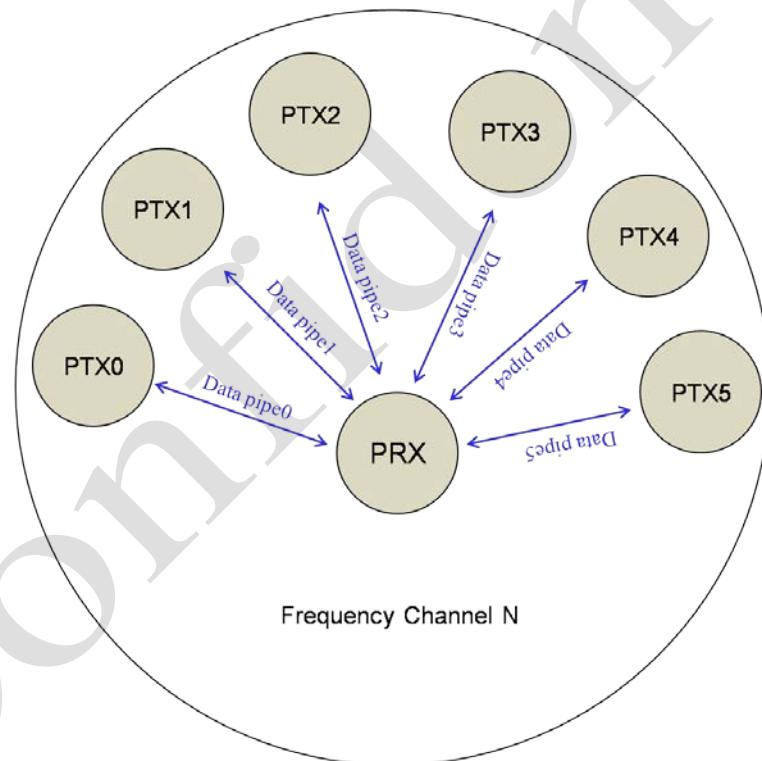

Fig.3.10 PRX using MultiSlave

The RF transceiver configured as PRX (primary receiver) can receive data addressed to six different data pipes in one frequency channel as shown in Figure 3.10. Each data pipe has its own unique address and can be configured for individual behavior.

Up to six RF transceivers configured as PTX can communicate with one RF transceiver configured as PRX. All data pipe addresses are searched for simultaneously. Only one data pipe can receive a packet at a time. All data pipes can perform Protocol engine functionality.

The following settings are common to all data pipes:

- CRC enabled/disabled (CRC always enabled when Protocol engine is enabled)
- CRC encoding scheme
- RX address width
- Frequency channel
- Air data rate
- LNA gain

The data pipes are enabled with the bits in the EN_RXADDR register. By default only data pipe 0 and 1 are enabled. Each data pipe address is configured in the RX_ADDR_PX registers.

Note: Always ensure that none of the data pipes have the same address.

Each pipe can have up to a 5 byte configurable address. Data pipes 0-5 share the four most significant address bytes. The LSByte must be unique for all six pipes. Figure 3.11 is an example of how data pipes 0-5 are addressed. Only pipe0 can have up to a 5 byte configurable address, other's pipes have 1bytes configurable address.

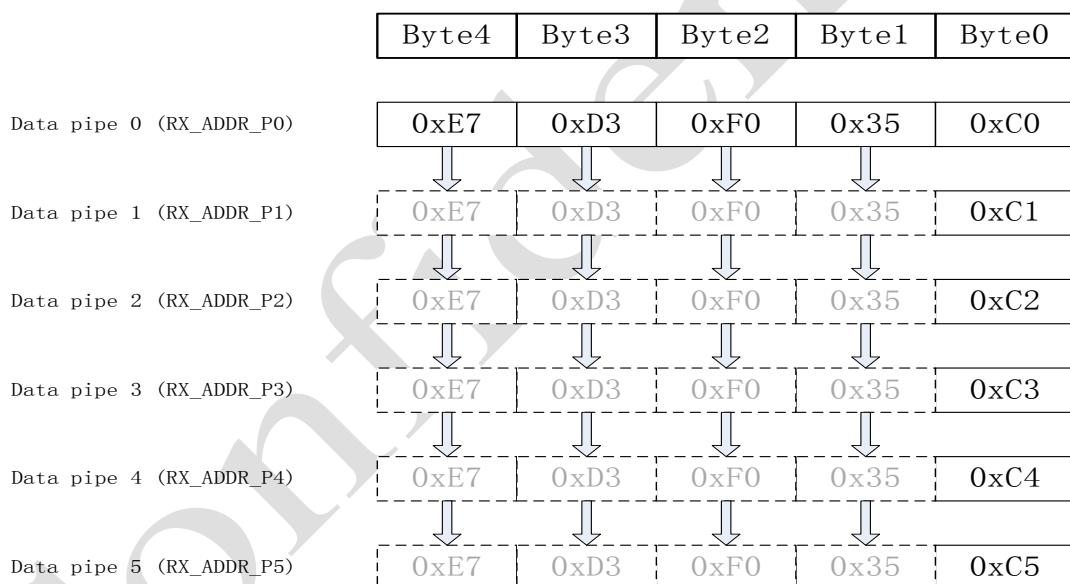

Figure 3.11 Addressing data pipes 0-5

The PRX, using MultiSlave and Protocol engine, receives packets from more than one PTX. To ensure that the ACK packet from the PRX is transmitted to the correct PTX, the PRX takes the data pipe address where it received the packet and uses it as the TX address when transmitting the ACK packet. Figure 3.12 is an example of an address configuration for the PRX and PTX. On the PRX the RX_ADDR_Px, defined as the pipe address, must be unique. On the PTX the TX_ADDR must be the same as the RX_ADDR_P0 and as the pipe address for the designated pipe.

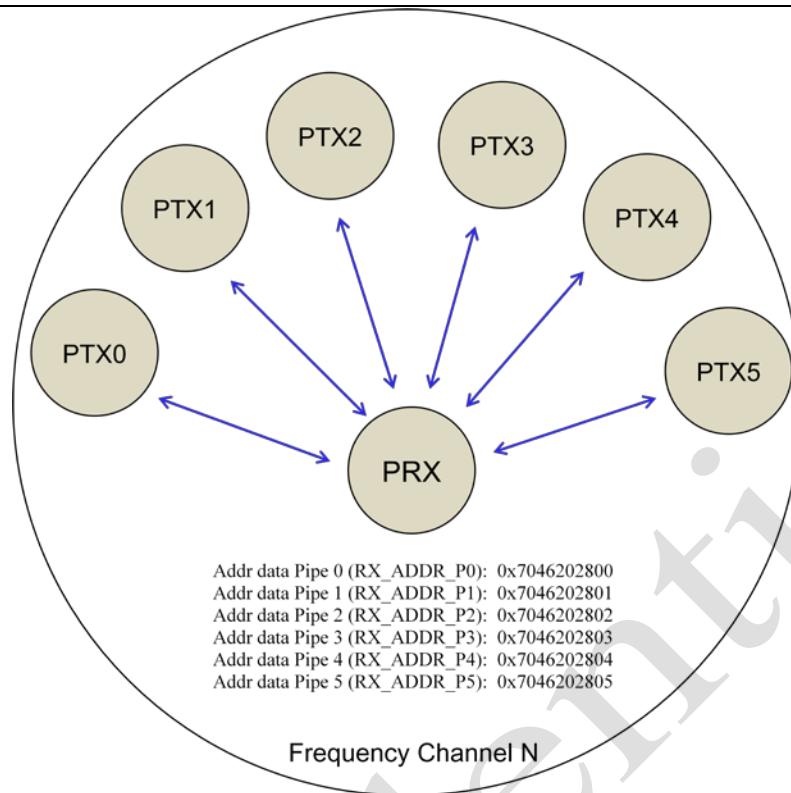

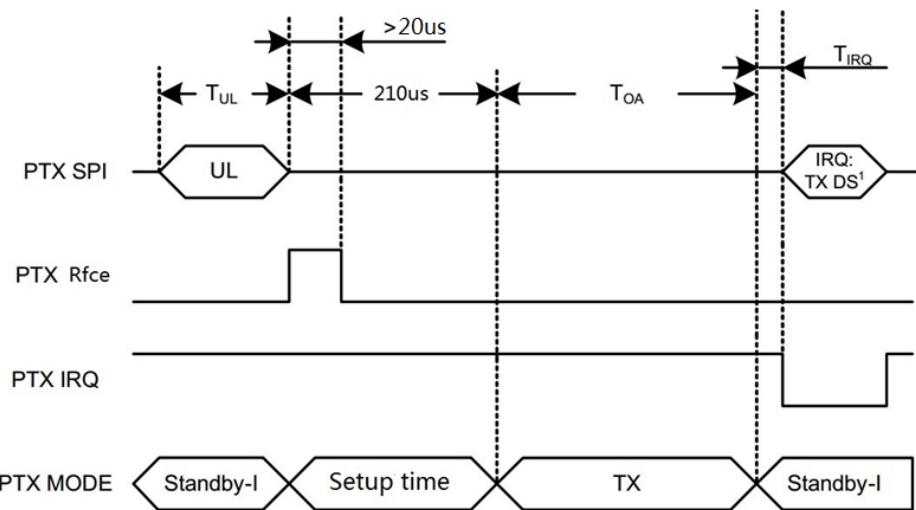

Figure 3.12 Example of data pipe addressing in MultiSlave

Only when a data pipe receives a complete packet can other data pipes begin to receive data. When multiple PTXs are transmitting to a PRX, the ARD can be used to skew the auto retransmission so that they only block each other once.

3.11 Protocol engine timing

This section describes the timing sequence of Protocol engine and how all modes are initiated and operated. The Protocol engine timing is controlled through the Data and Control interface. The RF transceiver can be set to static modes or autonomous modes where the internal state machine controls the events. Each autonomous mode/sequence ends with a RFIRQ interrupt. All the interrupts are indicated as IRQ events in the timing diagrams.

$T_{IRQ}=3\mu s$ @ 1Mbps, @2Mbps

Figure 3.13 Transmitting one packet with NO_ACK on

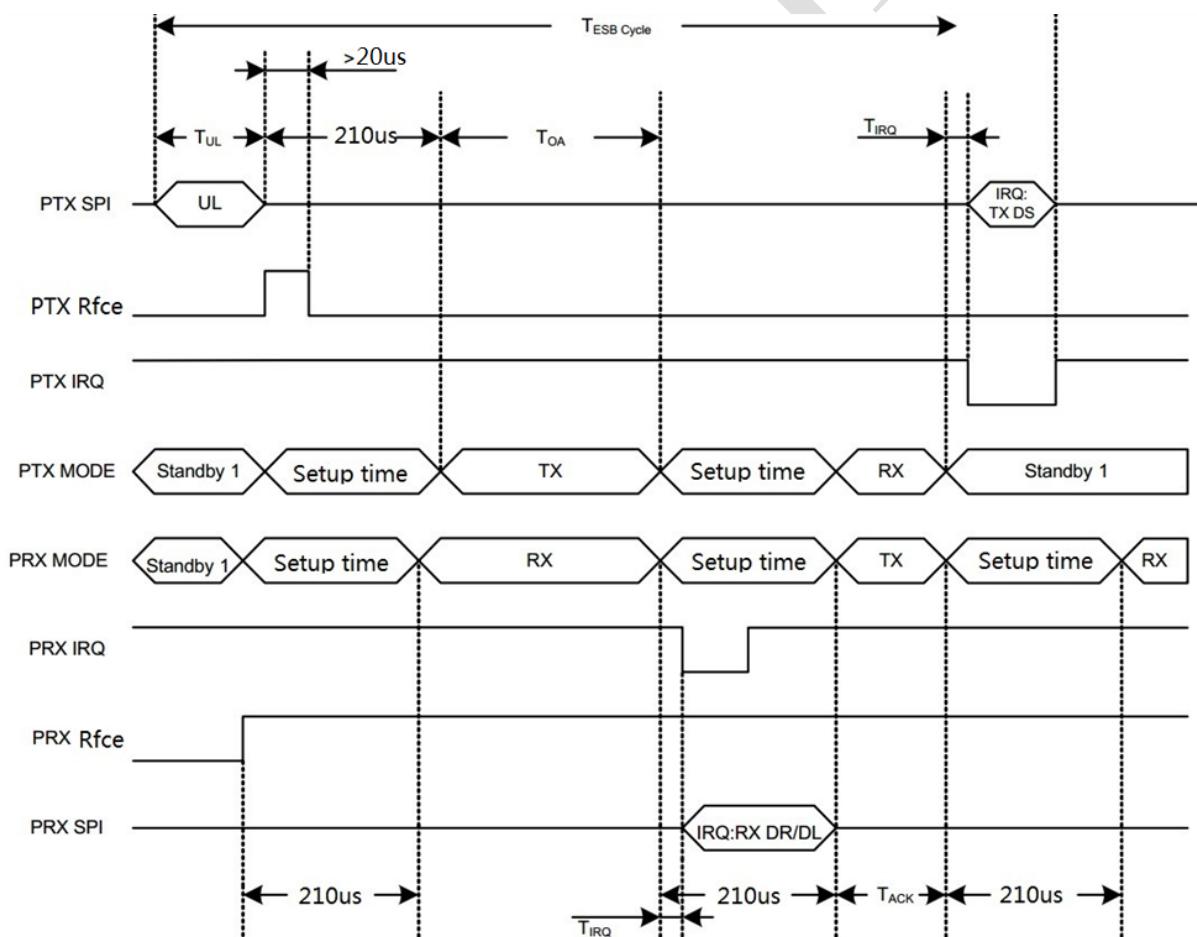

Figure 3.14 Timing of Protocol engine for one packet upload(2Mbps)

In Figure 3.14, the transmission and acknowledgement of a packet is shown. The PRX operation activates RX mode ($rfe=1$), and the PTX operation is activated in TX mode ($rfe=1$ for minimum $20\mu s$). After $210\mu s$ the transmission starts and finishes after the elapse of T_{OA} .

When the transmission ends the PTX operation automatically switches to RX mode to wait for the ACK packet from the PRX operation. When the PRX operation receives the packet it sets the interrupt for the host MCU and switches to TX mode to send an ACK. After the PTX operation receives the ACK packet it sets the interrupt to the MCU and clears the packet from the TX FIFO.

In Figure 3.15, the PTX timing of a packet transmission is shown when the first ACK packet is lost.

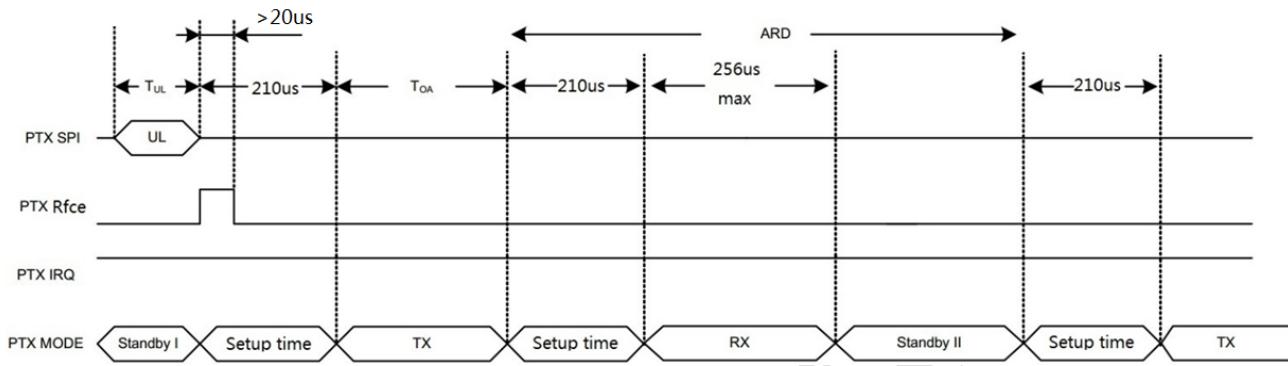

Figure 3.15 Timing of Protocol engine when the first ACK packet is lost (2 Mbps)

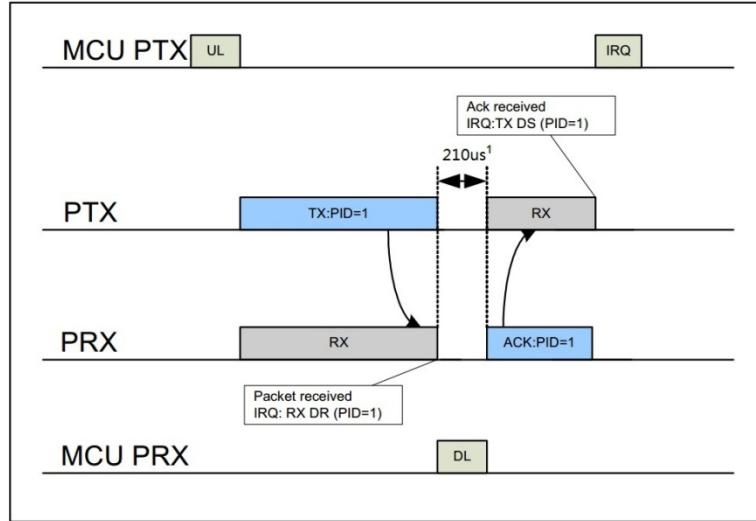

3.12 Protocol engine transaction diagram

This section describes several scenarios for the Protocol engine automatic transaction handling. The call outs in this section's figures indicate the IRQs and other events. For MCU activity the event may be placed at a different timeframe.

Note: The figures in this section indicate the earliest possible download (DL) of the packet to the MCU and the latest possible upload (UL) of payload to the transmitter.

3.12.1 Single transaction with ACK packet and interrupts

In Fig.3.16, the basic auto acknowledgement is shown. After the packet is transmitted by the PTX and received by the PRX the ACK packet is transmitted from the PRX to the PTX. The RX_DR IRQ is asserted after the packet is received by the PRX, whereas the TX_DS IRQ is asserted when the packet is acknowledged and the ACK packet is received by the PTX.

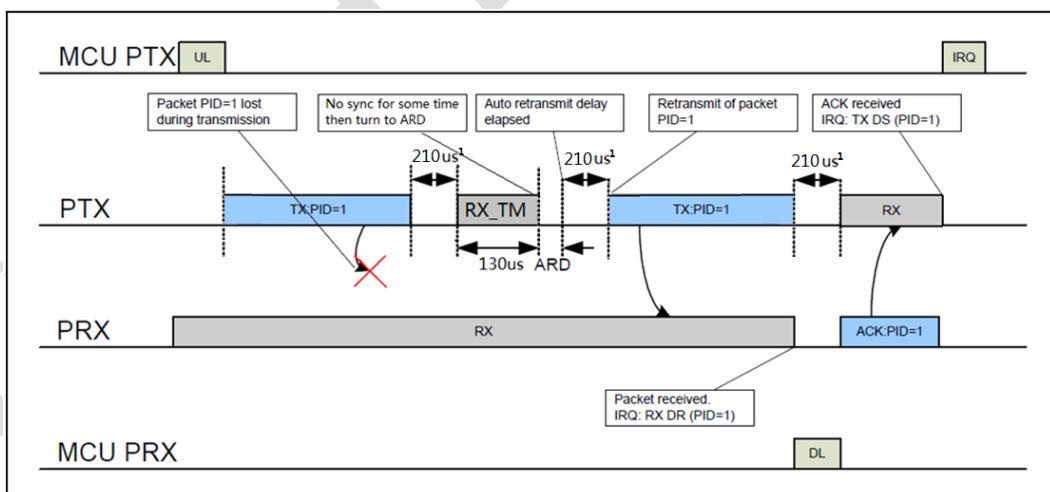

1 Radio Turn Around delay

Fig.3.16 TX/RX cycles with ACK and the according interrupts

3.12.2 Single transaction with a lost packet

Figure 3.17 is a scenario where a retransmission is needed due to loss of the first packet transmitted. After the packet is transmitted, the PTX enters RX mode to receive the ACK packet. After the first transmission, the PTX waits a specified time (including setup time, RX_TM and ARD) for the ACK packet, if it is not in the specific time slot the PTX retransmits the packet as shown in Figure 3.17. PTX will turn to RX mode after 210us setup time when packet is transmitted, after 130us RX timeout (RX_TM is RX timeout for PTX, it can be set shorter), then PTX turn to ARD (can be set to 0us, 256us, 512us to 3840us).

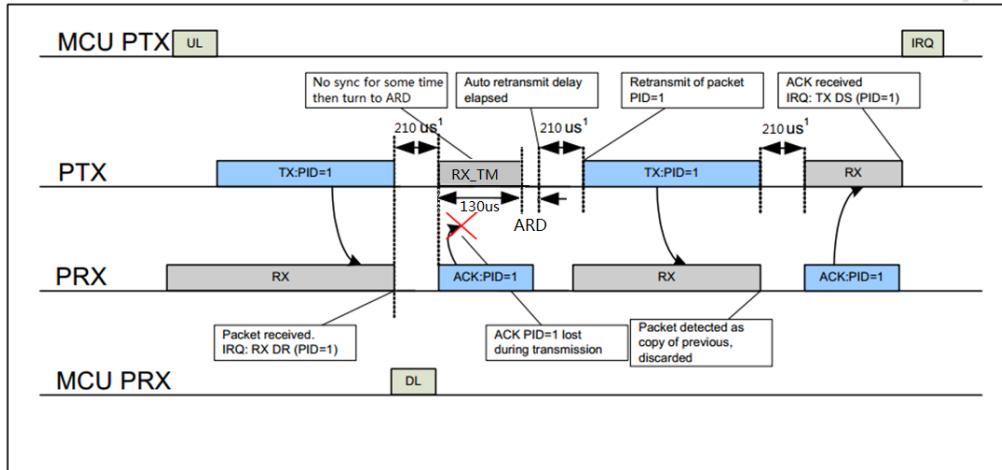

1 Radio Turn Around delay

Figure 3.17 TX/RX cycles with ACK and the according interrupts when the first packet transmit fails

When an address is detected the PTX stays in RX mode until the packet is received. When the retransmitted packet is received by the PRX (see Figure 3.17). The RX_DR IRQ is asserted and an ACK is transmitted back to the PTX. When the ACK is received by the PTX, the TX_DS IRQ is asserted.

3.12.3 Single transaction with a lost ACK packet

Figure 3.18 is a scenario where a retransmission is needed after a loss of the ACK packet. The corresponding interrupts are also indicated.

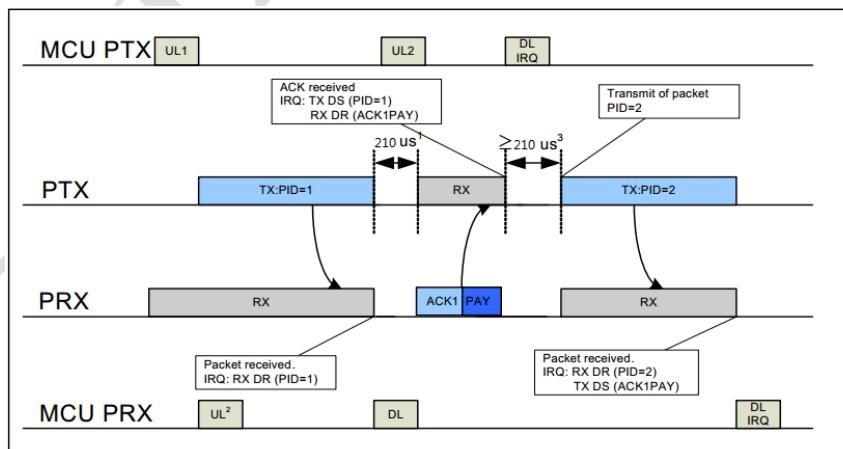

1 Radio Turn Around delay

Fig.3.18 TX/RX cycles with ACK and the according interrupts when the ACK packet fails

3.12.4 Single transaction with ACK payload packet

Figure 3.19 is a scenario of the basic auto acknowledgement with payload. After the packet is transmitted by the PTX and received by the PRX the ACK packet with payload is transmitted from the PRX to the PTX. The RX_DR IRQ is asserted after the packet is received by the PRX, whereas on the PTX side the TX_DS IRQ is asserted when the ACK packet is received by the PTX. On the PRX side, the TX_DS IRQ for the ACK packet payload is asserted after a new packet from PTX is received.

1 Radio Turn Around delay

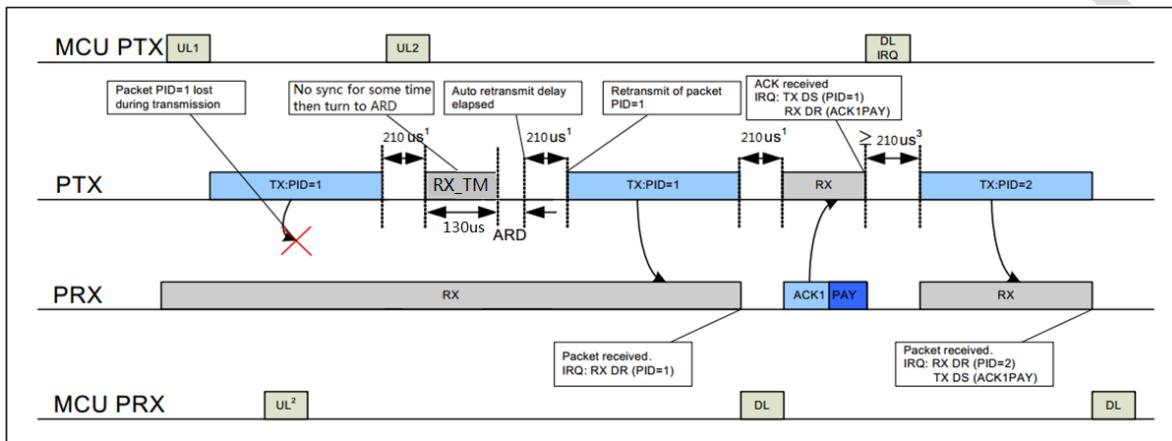

2 Uploading payload for Ack Packet

3 Delay defined by MCU on PTX side, $\geq 210\mu s$

Fig.3.19TX/RX cycles with ACK Payload and the according interrupts

3.12.5 Single transaction with ACK payload packet and lost packet

Figure 3.20 is a scenario where the first packet is lost and a retransmission is needed before the RX_DR IRQ on the PRX side is asserted. For the PTX both the TX_DS and RX_DR IRQ are asserted after the ACK packet is received. After the second packet (PID=2) is received on the PRX side both the RX_DR (PID=2) and TX_DS (ACK packet payload) IRQ are asserted.

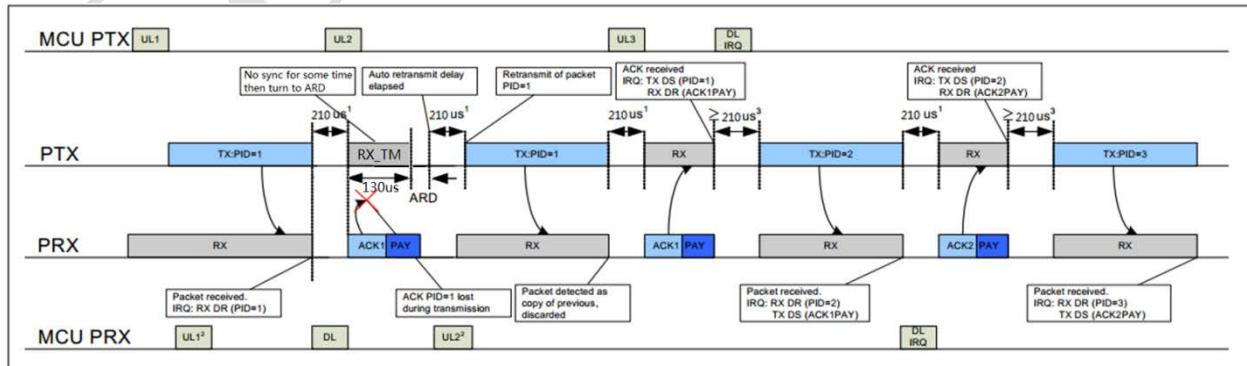

- 1 Radio Turn Around delay
 2 Uploading payload for Ack Packet
 3 Delay defined by MCU on PTX side, $\geq 210\mu s$

Fig.3.20TX/RX cycles and the according interrupt when the packet transmission fails

3.12.6 Two transactions with ACK payload packet and the first ACK packet lost

In Fig 3.21 the ACK packet is lost and a retransmission is needed before the TX_DS IRQ is asserted, but the RX_DR IRQ is asserted immediately. The retransmission of the packet (PID=1) results in a discarded packet. For the PTX both the TX_DS and RX_DR IRQ are asserted after the second transmission of ACK, which is received. After the second packet (PID=2) is received on the PRX both the RX_DR (PID=2) and TX_DS (ACK2PAY) IRQ is asserted. The callouts explains the different events and interrupts.

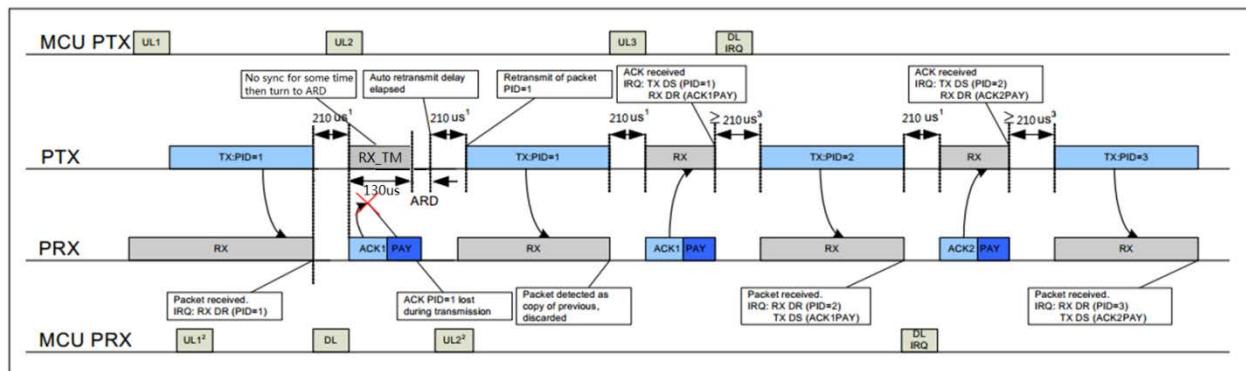

- 1 Radio Turn Around delay

2 Uploading payload for Ack Packet

3 Delay defined by MCU on PTX side, $\geq 210\text{us}$

Fig.3.21 TX/RX cycles with ACK Payload and the according interrupts when the ACK packet fails

3.12.7 Two transactions where max retransmissions is reached

1 Radio Turn Around delay

2 Uploading payload for Ack Packet

3 Delay defined by MCU on PTX side, $\geq 210\text{us}$

Fig 3.22 TX/RX cycles with ACK Payload and the according interrupts when the transmission fails. ARC is set to 2.

MAX_RT IRQ is asserted if the auto-retransmit counter (ARC_CNT) exceeds the programmed maximum limit (ARC). In Fig 3.22, the packet transmission ends with a MAX_RT IRQ. The payload in TX FIFO is NOT removed and the MCU decides the next step in the protocol. A toggle of the rfce bit in the RFCON register starts a new transmitting sequence of the same packet. The payload can be removed from the TX FIFO using the FLUSH_TX command.

3.13 Data and control interface

The data and control interface gives you access to all the features in the RF transceiver. Compared to the standalone component SFR registers are used instead of port pins. Otherwise the interface is identical to the standalone HS6206 chip.

3.13.1 SFR registers

Address (Hex)	Name/mnemonic	Bit	Reset Value	Type	Description
0xE5	SPIRCON	3:0	0x0F	R/W	SPI MASTER configuration register1
	maskIrqRx_fifoFull	3	1	R/W	1: Disable interrupt when RX FIFO is full. 0: Enable interrupt when RX FIFO is full.
	maskIrqRxDa_taReady	2	1	R/W	1: Disable interrupt when data is available in RX FIFO. 0: Enable interrupt when data is available in RX FIFO.
	maskIrqTx_fifoEmpty	1	1	R/W	1: Disable interrupt when TX FIFO is empty.

					0: Enable interrupt when TX FIFO is empty.
	maskIrqTxFifo Ready	0	1	R/W	1: Disable interrupt when a location is available in TX FIFO. 0: Enable interrupt when a location is available in TX FIFO.
0xE6	SPIRSTAT	3:0	0x03	R	SPI Mater status register
	Rxfifo_full	3	0	R	1: RX FIFO full. 0: RX FIFO can accept more data from SPI.
	Rxdata_ready	2	0	R	1: Data available in RX FIFO. 0: No data in RX FIFO.
	Txfifo_empty	1	1	R	1: TX FIFO empty. 0: Data in TX FIFO.
	Txfifo_ready	0	1	R	1: Location available in TX FIFO. 0: TX FIFO full.
0xE7	SPIRDAT	7:0	0x00	R/W	SPI Master data register. Accesses TX (write) and RX (read) FIFO buffers, both two bytes deep.
0xE8	RFCON	1:0	0x2	R/W	
	Rfcsn	1	1	R/W	Enable RF command. 0: enabled
	rfce	0	0	R/W	Enable RF transceiver. 1: enabled

The RF transceiver SPI Master is configured through SPIRCON1. After transferred one byte can generate interrupt (MSDONE), unless they are masked by their respective bits in SPIRCON1. SPIRSTAT reveals which sources these are active.

SPIRDAT accesses both the TX (write) and the RX (read) FIFOs, which are two bytes deep. The FIFOs are dynamic and can be refilled according to the state of the status flags: “FIFO ready” means that the FIFO can accept data. Data ready means that the FIFO can provide data, minimum one byte. **RFCON** controls the RF transceiver SPI Slave chip select signal (rfcsn), the RF transceiver chip enable signal (rfce).

3.13.2 SPI Operation

This section describes the SPI commands and timing.

3.13.2.1 SPI commands

The SPI commands are shown in Table 3.5. Every new command must be started by writing 0 to rfcsn in the RFCON register.

The SPI command is transferred to RF transceiver by writing the command to the SPIRDAT register. After the first transfer the RF transceiver's STATUS register can be read from SPIRDAT when the transfer is completed.

The serial shifting SPI commands is in the following format:

<Command word: MSBit to LSBit (one byte)>

<Data bytes: MSBit in each byte first>

Command	Command word (binary)	#Data bytes	Operation
---------	-----------------------	-------------	-----------

HS6206

R_REGISTER	000A AAAA	1 to 5 LSByte first	Read command and status registers. AAAAA=5 bit register map address
W_REGISTER	001A AAAA	1 to 5 LSByte first	Read command and status registers. AAAAA=5 bit register map address Executable in power down or standby modes only.
R_RX_PAYLOAD	0110 0001	1 to 32 LSByte first	Read RX-payload: 1-32 bytes. A read operation always starts at byte 0. Payload is deleted from FIFO after it is read. Used in RX mode.
W_TX_PAYLOAD	1010 0000	1 to 32 LSByte first	Write TX-payload: 1 – 32 bytes. A write operation always starts at byte 0 used in TX payload.
FLUSH_TX	1110 0001	0	Flush TX FIFO, used in TX mode
FLUSH_RX	1110 0010	0	Flush TX FIFO, used in TX mode Should not be executed during transmission of acknowledge, that is, acknowledge package will not be completed
REUSE_TX_PL	1110 0011	0	Used for a PTX operation Reuse last transmitted payload. TX payload reuse is active until W_TX_PAYLOAD or FLUSH TX is executed. TX payload reuse must not be activated or deactivated during package transmission.
R_RX_PL_WID	0110 0000	1	Read RX payload width for the top R_RX_PAYLOAD in the RX FIFO. Note: Flush RX FIFO if the read value is larger than 32 bytes.
W_ACK_PAYLOAD	1010 1PPP	1 to 32 LSByte first	Used in RX mode. Write Payload to be transmitted together with ACK packet on PIPE PPP. (PPP valid in the range from 000 to 101). Maximum three ACK packet payloads can be pending. Payloads with same PPP are handled using first in - first out principle. Write payload: 1– 32 bytes. A write operation always starts at byte 0.
W_TX_PAYLOAD_NO_ACK	1011 0000	1 to 32 LSByte first	Used in TX mode. Disables AUTOACK on this specific packet specific packet.
NOP	1111 1111	0	No Operation. Might be used to read the STATUS register

Tab.3.5Command set for the RF transceiver SPI

The W_REGISTER and R_REGISTER commands operate on single or multi-byte registers. When accessing multi-byte registers read or writes to the MSBit of LSByte first. You can terminate the writing before all bytes in a multi-byte register are written, leaving the unwritten MSByte(s) unchanged. For example, the LSByte of RX_ADDR_P0 can be modified by writing only one byte to the RX_ADDR_P0 register. The content of the status register is always read to MISO after a high to low transition on CSN.

Note: The 3 bit pipe information in the STATUS register is updated during the RFIRQ high to low transition. The pipe information is unreliable if the STATUS register is read during an RFIRQ high to low transition.

3.13.3 Data FIFO

The data FIFOs store transmitted payloads (TX FIFO) or received payloads that are ready to be clocked out (RX FIFO). The FIFOs are accessible in both PTX mode and PRX mode. The following FIFOs are present in the RF transceiver:

- ◆ TX three level, 32 byte FIFO
- ◆ RX three level, 32 byte FIFO

Both FIFOs have a controller and are accessible through the SPI by using dedicated SPI commands. A TX FIFO in PRX can store payloads for ACK packets to three different PTX devices. If the TX FIFO contains more than one payload to a pipe, payloads are handled using the first in - first out principle. The TX FIFO in a PRX is blocked if all pending payloads are addressed to pipes where the link to the PTX is lost. In this case, the MCU can flush the TX FIFO using the FLUSH_TX command.

The RX FIFO in PRX can contain payloads from up to three different PTX devices and a TX FIFO in PTX can have up to three payloads stored.

You can write to the TX FIFO using these three commands; W_TX_PAYLOAD and W_TX_PAYLOAD_NO_ACK in PTX mode and W_ACK_PAYLOAD in PRX mode. All three commands provide access to the TX_PLD register.

The RX FIFO can be read by the command R_RX_PAYLOAD in PTX and PRX mode. This command provides access to the RX_PLD register.

The payload in TX FIFO in a PTX is not removed if the MAX_RT IRQ is asserted.

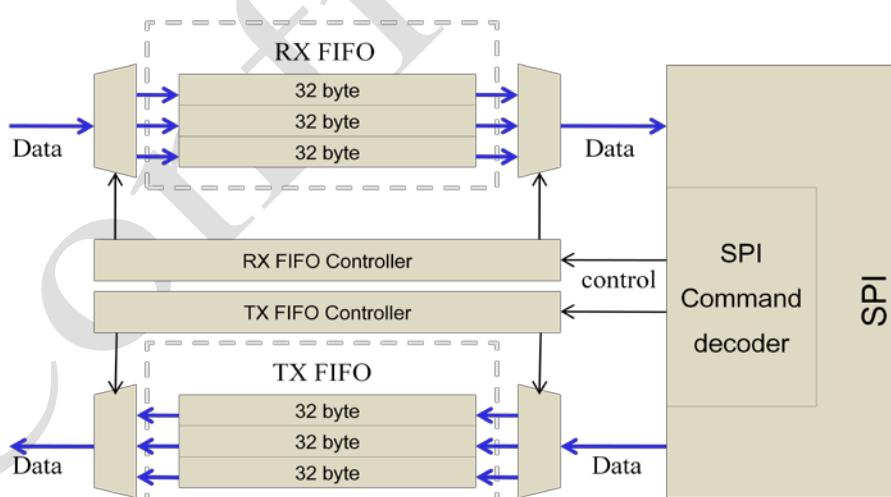

Figure 3.23 FIFO (RX and TX) block diagram

You can read if the TX and RX FIFO are full or empty in the FIFO_STATUS register.

3.13.4 Interrupt

The RF transceiver can send interrupts to the MCU. The interrupt (RFIRQ) is activated when TX_DS, RX_DR or MAX_RT are set high by the state machine in the STATUS register. RFIRQ is deactivated when the MCU writes '1' to the interrupt source bit in the STATUS register. The interrupt mask in the CONFIG register is used to select the IRQ sources that are allowed to activate RFIRQ. By setting one of the mask bits high, the corresponding interrupt source is disabled. By default all interrupt sources are enabled.

Note: The 3 bit pipe information in the STATUS register is updated during the RFIRQ high to low transition. The pipe information is unreliable if the STATUS register is read during a RFIRQ high to low transition.

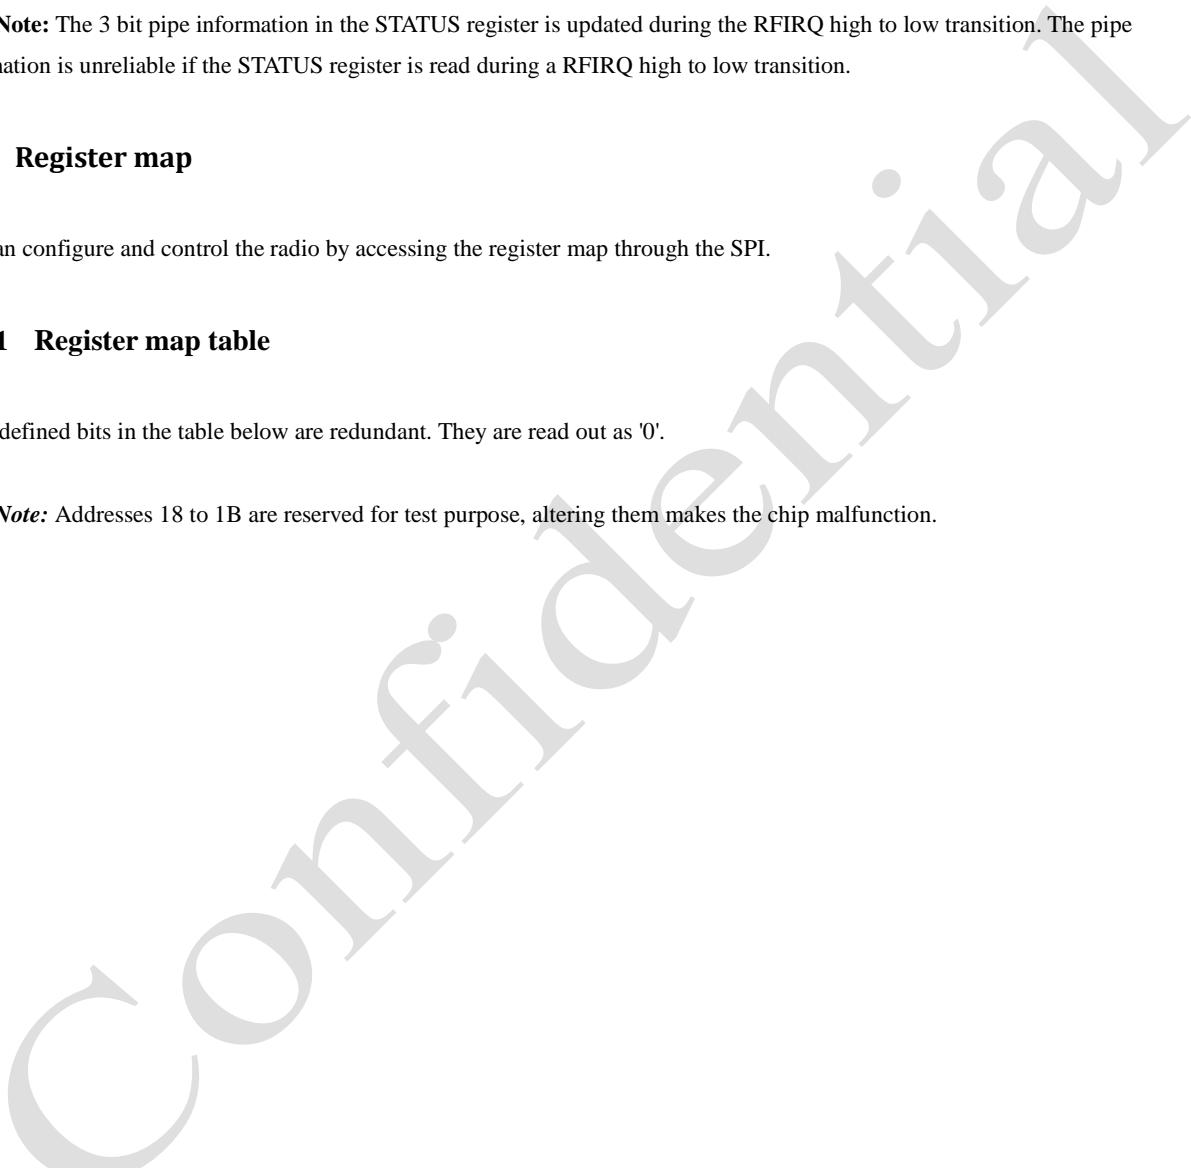

3.14 Register map

You can configure and control the radio by accessing the register map through the SPI.

3.14.1 Register map table

All undefined bits in the table below are redundant. They are read out as '0'.

Note: Addresses 18 to 1B are reserved for test purpose, altering them makes the chip malfunction.

Description of Word

Bit	Value	Symbol	Description		
7	0	BANK	Register BANK status		
			1	Register R/W is to register BANK1	
			0	Register R/W is to register BANK0	
6	0	RX_DR	Data Ready RX FIFO interrupt. Asserted when new data arrives RX FIFO Write 1 to clear bit.		
5	0	TX_DS	Data Sent TX FIFO interrupt. Asserted when packet transmitted on TX. If AUTO_ACK is activated, this bit is set high only when ACK is received. Write 1 to clear bit.		
4	0	MAX_RT	Maximum number of TX retransmits interrupt Write 1 to clear bit. If MAX_RT is asserted it must be cleared to enable further communication.		
3:1	3'b111	RX_P_NO	Data pipe number for the payload available for reading from RX_FIFO		
			111	RX FIFO Empty	
			110	Not Used	
			000-101	Data Pipe Number	
0	0	TX_FULL	TX FIFO full flag		
			0	Available locations in TX FIFO	
			1	TX FIFO full

4 MCU

4.1 Block diagram

4.2 Features

- Control Unit
 - 8-bit instruction decoder
 - Reduced instruction cycle time (up to 12 times in respect to standard 80C51)
- Arithmetic-Logic Unit
 - 8-bit arithmetic and logical operations
 - Boolean manipulations
- Three 16-bit Timers/Counters
 - 80C51-like Timer 0 & 1
 - 80515-like Timer 2
- Compare/Capture Unit, dedicated to Timer 2
 - Software control capture
- Full Duplex Serial Interfaces
 - Serial 0 (80C51-like)
 - Synchronous mode, fixed baud rate
 - 8-bit UART mode, variable baud rate
 - 9-bit UART mode, fixed baud rate
 - 9-bit UART mode, variable baud rate
 - Baud Rate Generator
- Interrupt Controller
 - Four Priority Levels with 13 interrupt sources
- Memory interface
 - 16-bit address bus
 - Dual Data Pointer for fast data block transfer

4.3 Instructions in Functional Order

4.3.1 Arithmetic Operations

Mnemonic	Description	Code	Bytes	Cycles
ADD A,Rn	Add register to accumulator	0x28-0x2F	1	1
ADD A,direct	Add directly addressed data to accumulator	0x25	2	2
ADD A,@Ri	Add indirectly addressed data to accumulator	0x26-0x27	1	2
ADD A,#data	Add immediate data to accumulator	0x24	2	2
ADDC A,Rn	Add register to accumulator with carry	0x38-0x3F	1	1
ADDC A,direct	Add directly addressed data to accumulator with carry	0x35	2	2
ADDC A,@Ri	Add indirectly addressed data to accumulator with carry	0x36-0x37	1	2
ADDC A,#data	Add immediate data to accumulator with carry	0x34	2	2

SUBB A,Rn	Subtract register from accumulator with borrow	0x98-0x9F	1	1
SUBB A,direct	Subtract directly addressed data from accumulator with borrow	0x95	2	2
SUBB A,@Ri	Subtract indirectly addressed data from accumulator with borrow	0x96-0x97	1	2
SUBB A,#data	Subtract immediate data from accumulator with borrow	Ox94	2	2
INC A	Increment accumulator	0x04	1	1
INC Rn	Increment register	0x08-0x0F	1	1
INC direct	Increment directly addressed location	0x05	2	2
INC @Ri	Increment indirectly addressed location	0x06-0x07	1	2
INC DPTR	Increment data pointer	0xA3	1	1
DEC A	Decrement accumulator	0x14	1	1
DEC Rn	Decrement register	0x18-0x1F	1	1
DEC direct	Decrement directly addressed location	0x15	2	2
DEC @Ri	Decrement indirectly addressed location	0x16-0x17	1	2
MUL AB	Multiply A and B	0xA4	1	4
DIV	Divide A by B	0x84	1	4
DA A	Decimally adjust accumulator	0xD4	1	1

4.3.2 Logic Operations

Mnemonic	Description	Code	Bytes	Cycles
ANL A,Rn	AND register to accumulator	0x58-0x5F	1	1
ANL A,direct	AND directly addressed data to accumulator	0x55	2	2
ANL A,@Ri	AND indirectly addressed data to accumulator	0x56-0x57	1	2
ANL A,#data	AND immediate data to accumulator	0x54	2	2
ANL direct,A	AND accumulator to directly addressed location	0x52	2	2
ANL direct,#data	AND immediate data to directly addressed location	0x53	3	3
ORL A,Rn	OR register to accumulator	0x48-0x4F	1	1
ORL A,direct	OR directly addressed data to accumulator	0x45	2	2
ORL A,@Ri	OR indirectly addressed data to accumulator	0x46-0x47	1	2
ORL A,#data	OR immediate data to accumulator	0x44	2	2
ORL direct,A	OR accumulator to directly addressed location	0x42	2	2
ORL direct,#data	OR immediate data to directly addressed location	0x43	3	3
XRL A,Rn	Exclusive OR register to accumulator	0x68-0x6F	1	1
XRL A,direct	Exclusive OR directly addressed data to accumulator	0x65	2	2
XRL A,@Ri	Exclusive OR indirectly addressed data to accumulator	0x66-0x67	1	2
XRL A,#data	Exclusive OR immediate data to accumulator	0x64	2	2
XRL direct,A	Exclusive OR accumulator to directly addressed location	0x62	2	2
XRL direct,#data	Exclusive OR immediate data to directly addressed location	0x63	3	3

CLR A	Clear accumulator	0xE4	1	1
CPL A	Complement accumulator	0xF4	1	1
RLA	Rotate accumulator left	0x23	1	1
RLCA	Rotate accumulator left through carry	0x33	1	1
RR A	Rotate accumulator right	0x03	1	1
RRC A	Rotate accumulator right through carry	0x13	1	1
SWAP A	Swap nibbles within the accumulator	0xC4	1	1

4.3.3 Data Transfer Operations

Mnemonic	Description	Code	Bytes	Cycles
MOV A,Rn	Move register to accumulator	0xE8-0xEF	1	1
MOV A,direct	Move directly addressed data to accumulator	0xE5	2	2
MOV A,@Ri	Move indirectly addressed data to accumulator	0xE6-0xE7	1	2
MOV A,#data	Move immediate data to accumulator	0x74	2	2
MOV Rn,A	Move accumulator to register	0xF8-0xFF	1	1
MOV Rn,direct	Move directly addressed data to register	0xA8-0xAF	2	2
MOV Rn,#data	Move immediate data to register	0x78-0x7F	2	2
MOV direct,A	Move accumulator to direct	0xF5	2	2
MOV direct,Rn	Move register to direct	0x88-0x8F	2	2
MOV direct1,direct2	Move directly addressed data to directly addressed location	0x85	3	3
MOV direct,@Ri	Move indirectly addressed data to directly addressed location	0x86-0x87	2	2
MOV direct,#data	Move immediate data to directly addressed location	0x75	3	3
MOV @Ri,A	Move accumulator to indirectly addressed location	0xF6-0xF7	1	1
MOV @Ri,direct	Move directly addressed data to indirectly addressed location	0xA6-0xA7	2	2
MOV @Ri,#data	Move immediate data to indirectly addressed location	0x76-0x77	2	2
MOV DPTR,#data16	Load data pointer with a 16-bit immediate	0x90	3	3
MOVCA,@A+DPTR	Load accumulator with a code byte relative to DPTR	0x93	1	3
MOVC A,@A+PC	Load accumulator with a code byte relative to PC	0x83	1	3
MOVX A,@Ri	Move external RAM (8-bit addr.) to accumulator	0xE2-0xE3	1	3-10
MOVX A,@DPTR	Move external RAM (16-bit addr.) to accumulator	0xE0	1	3-10
MOVX @Ri,A	Move accumulator to external RAM (8-bit addr.)	0xF2-0xF3	1	3-12
MOVX @DPTR,A	Move accumulator to external RAM (16-bit addr.)	0xF0	1	3-12
PUSH direct	Push directly addressed data onto stack	0xC0	2	2
POP direct	Pop directly addressed location from stack	0xD0	2	2
XCH A,Rn	Exchange register with accumulator	0xC8-0xCF	1	1
XCH A,direct	Exchange directly addressed location with accumulator	0xC5	2	2
XCH A,@Ri	Exchange indirect RAM with accumulator	0xC6-0xC7	1	2
XCHD A,@Ri	Exchange low-order nibbles of indirect and accumulator	0xD6-0xD7	1	2

Note:

- a、The MOVX instructions perform one of two actions depending on the state of “pmw” bit (pcon.4).

4.3.4 Program Branches

Mnemonic	Description	Code	Bytes	Cycles
ACALL addr11	Absolute subroutine call	xxx10001b	2	2
LCALL addr16	Long subroutine call	0x12	3	3
RET	Return from subroutine	0x22	1	4
RETI	Return from interrupt	0x32	1	4
AJMP addr11	Absolute jump	xxx00001b	2	2
LJMP addr16	Long jump	0x02	3	3
SJMP rel	Short jump (relative address)	0x80	2	2
JMP @A+DPTR	Jump indirect relative to the DPTR	0x73	1	3
JZ rel	Jump if accumulator is zero	0x60	2	3
JNZ rel	Jump if accumulator is not zero	0x70	2	3
JC rel	Jump if carry flag is set	0x40	2	3
JNC	Jump if carry flag is not set	0x50	2	3
JB bit,rel	Jump if directly addressed bit is set	0x20	3	4
JNB bit,rel	Jump if directly addressed bit is not set	0x30	3	4
JBC bit,rel	Jump if directly addressed bit is set and clear bit	0x10	3	4
CJNE A,direct,rel	Compare directly addressed data to accumulator and jump if not equal	0xB5	3	4
CJNE A,#data,rel	Compare immediate data to accumulator and jump if not equal	0xB4	3	4
CJNERn,#data,rel	Compare immediate data to register and jump if not equal	0xB8-0xBF	3	4
CJNE @Ri,#data,rel	Compare immediate to indirect and jump if not equal	B6-B7	3	5
DJNZ Rn,rel	Decrement register and jump if not zero	D8-DF	2	3
DJNZ direct,rel	Decrement directly addressed location and jump if not zero	D5	3	4
NOP	No operation	00	1	1

4.3.5 Boolean Manipulation

Mnemonic	Description	Code	Bytes	Cycles
CLR C	Clear carry flag	0xC3	1	1

CLR bit	Clear directly addressed bit	0xC2	2	2
SETB C	Set carry flag	0xD3	1	1
SETB bit	Set directly addressed bit	0xD2	2	2
CPL C	Complement carry flag	0xB3	1	2
CPL bit	Complement directly addressed bit	0xB2	2	2
ANL C,bit	AND directly addressed bit to carry flag	0x82	2	2
ANL C,/bit	AND complement of directly addressed bit to carry	0xB0	2	2
ORL C,bit	OR directly addressed bit to carry flag	0x72	2	2
ORL C,/bit	OR complement of directly addressed bit to carry	0xA0	2	2
MOV C,bit	Move directly addressed bit to carry flag	0xA2	2	2
MOV bit,C	Move carry flag to directly addressed bit	0x92	2	2

The duration of each instruction can be calculated using the formula below.

If (BYTES > 1 or CYCLES = 1) then

$$\text{DURATION} = \text{CYCLES} + (\text{BYTES} + R) * P + X * D$$

else

$$\text{DURATION} = \text{CYCLES} + (2 + R) * P + X * D$$

Where:

- BYTES is the number of bytes for the instruction (see tables above)
- CYCLES is the number of cycles for no wait states (see tables above)
- R = 1 for the MOVC instruction, otherwise R = 0
- X = 1 for MOVX instructions, otherwise X = 0
- P = number of program memory wait states (= “ckcon[6:4]”)
- D = number of data memory wait states (= “ckcon[2:0]”).

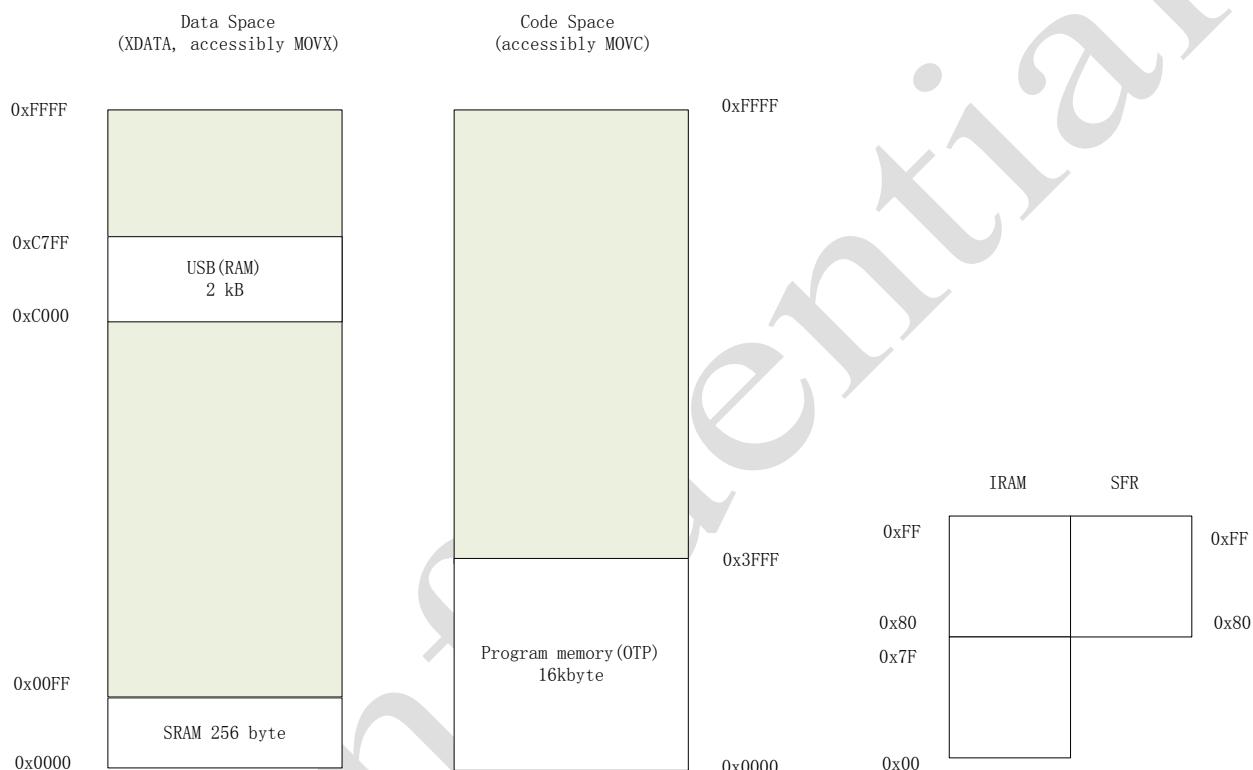

In the Program Memory Write mode (PMW) the formula for MOVX is as follows:

$$\text{DURATION} = \text{CYCLES} + (2 + X) * P$$

5 Memory and I/O organization

The MCU has 64 kB of separate address space for code and data, an area of 256 byte for internal data (IRAM) and an area of 128 byte for Special Function Registers (SFR).

The memory block has a default setting of 16 kB program memory (OTP) and 256 byte of user memory (SRAM) see default memory map in Figure 1.

The lower 128 bytes of the IRAM contains work registers (0x00–0x1F) and bit addressable memory (0x20–0x2F). The upper half can only be accessed by indirect addressing.

The lowest 32 bytes of the IRAM form four banks, each consisting of eight registers (R0–R7). Two bits of the program memory status word (PSW) select which bank is used. The next 16 bytes of memory form a block of bit-addressable memory, accessible through bit addresses 0x00–0x7.

5.1 CPU Special Function Registers

5.1.1 Accumulator – ACC

Accumulator is used by most of the MCU instructions to hold the operand and to store the result of an operation. The mnemonics for

accumulator specific instructions refer to accumulator as A, not ACC.

Address	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0xE0	acc.7	acc.6	acc.5	acc.4	acc.3	acc.2	acc.1	acc.0

5.1.2 B register – B

The B register is used during multiplying and division instructions. It can also be used as a scratch-pad register to hold temporary data.

Address	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
0xF0	b.7	b.6	b.5	b.4	b.3	b.2	b.1	b.0

5.1.3 Program Status Word Register – PSW

The PSW register contains status bits that reflect the current state of the MCU.

Note: The Parity bit can only be modified by hardware upon the state of ACC register.

Address	Bit	Name	Description
0xD0	7	cy	Carry flag: Carry bit in arithmetic operations and accumulator for Boolean operations.
	6	ac	Auxiliary Carry flag: Set if there is a carry-out from 3 rd bit of Accumulator in BCD operations
	5	f0	General purpose flag 0
	4:3	rs	Register bank select, bank 0..3 (0x00–0x07, 0x08–0x0f, 0x10–0x17, 0x18–0x1f)
	2	ov	Overflow flag: Set if overflow in Accumulator during arithmetic operations
	1	f1	General purpose flag 1
	0	p	Parity flag: Set if odd number of ‘1’ in ACC

5.1.4 Stack Pointer – SP

This register points to the top of stack in internal data memory space. It is used to store the return address of a program before executing interrupt routine or subprograms. The SP is incremented before executing PUSH or CALL instruction and it is decremented after executing POP or RET(I) instruction (it always points to the top of stack).

Address	Register name
0x81	SP

5.1.5 Data Pointer – DPH, DPL

Address	Register name
0x82	DPL
0x83	DPH

The Data Pointer Registers can be accessed through DPL and DPH. The actual data pointer is selected by DPS register. These registers are intended to hold 16-bit address in the indirect addressing mode used by MOVX (move external memory), MOVC (move program memory) or JMP (computed branch) instructions. They may be manipulated as 16-bit register or as two separate 8-bit registers. DPH holds higher byte and DPL holds lower byte of indirect address. It is generally used to access external code or data space (for example, MOVC A, @A+DPTR or MOV A, @DPTR respectively).

5.1.6 Data Pointer 1 – DPH1, DPL1

Address	Register name
0x84	DPL1
0x85	DPH1

The Data Pointer Register 1 can be accessed through DPL1 and DPH1. The actual data pointer is selected by DPS register. These registers are intended to hold 16-bit address in the indirect addressing mode used by MOVX (move external memory), MOVC (move program memory) or JMP (computed branch) instructions. They may be manipulated as 16-bit register or as two separate 8-bit registers. DPH1 holds higher byte and DPL1 holds lower byte of indirect address. It is generally used to access external code or data space (for example, MOVC A,@A+DPTR or MOV A,@DPTR respectively). The Data Pointer 1 is an extension to the standard 8051 architecture to speed up block data transfers.

5.1.7 Data Pointer Select Register – DPS

The MCU contains two Data Pointer registers. Both of them can be used as 16-bits address source for indirect addressing. The DPS register serves for selecting active data pointer register.

Address	Bit	Name	Description
0x92	7:1	-	Not used
	0	dps	Data Pointer Select. 0: select DPH:DPL, 1: select DPH1:DPL1

5.1.8 PCON register

The PCON register is used to control the Program Memory Write Mode and Serial Port 0 baud rate select.

Default value: 0x08

Address	Bit	Name	Description
0x87	7	smod	Serial port 0 baud rate select
	6	-	Not used
	5	isr_tm	Interrupt Service Routine Test Mode flag: When set to 1, the interrupt vectors assigned to Timer 0 & 1, Serial Port 0 & 1 interfaces can be triggered only with the use of external inputs of the core
	4	pmw	Program memory write mode: 1: MOVX instructions will access memory code space 0: MOVX instructions will access memory data space
	3	-	Not used
	2	gf0	General purpose flag 0
	1	-	Not used. This bit must always be cleared. Always read as 0.
	0	-	Not used. This bit must always be cleared. Always read as 0.

5.1.9 Clock Control Register – CKCON

The content of this register defines the number of internally generated wait states that occur during read/write accesses to external data and program memory. It also controls the type of write access to either of the memory spaces.

Default value: 0x71

Address	Bit	Name	Description
0x8E	7	-	Keep setting 1
	6:4	pw	Program memory wait state control
	3	-	Keep setting 1
	2:0	ds	External data memory stretch cycle control.

5.1.10 Software Reset Register SRST

The software reset will be accomplished through the SRST SFR register. The contents of this register are presented below.

Address	Bit	Name	Description
0xF7	7:1	-	Not used

		0	srstreq	Software reset request. Writing ‘0’ value to this bit will have no effect. Single writing ‘1’ value to this bit will have no effect. Double writing ‘1’ value (in two consecutive instructions) will generate an internal software reset. Reading this bit will inform about the reset source: if ‘0’ – source of last reset sequence was not a software reset (hardware, watchdog or pin reset); If ‘1’ – source of last reset sequence was a software reset (caused by double writing ‘1’ value to the “srstreq” bit).					
--	--	---	---------	--	--	--	--	--	--

6 OTP memory

This section describes the operation of the embedded OTP (One Time Programmable) memory. The primary use for this memory is for read only program and data storage, but the MCU may also perform write operations, for instance to store pairing information persistently.

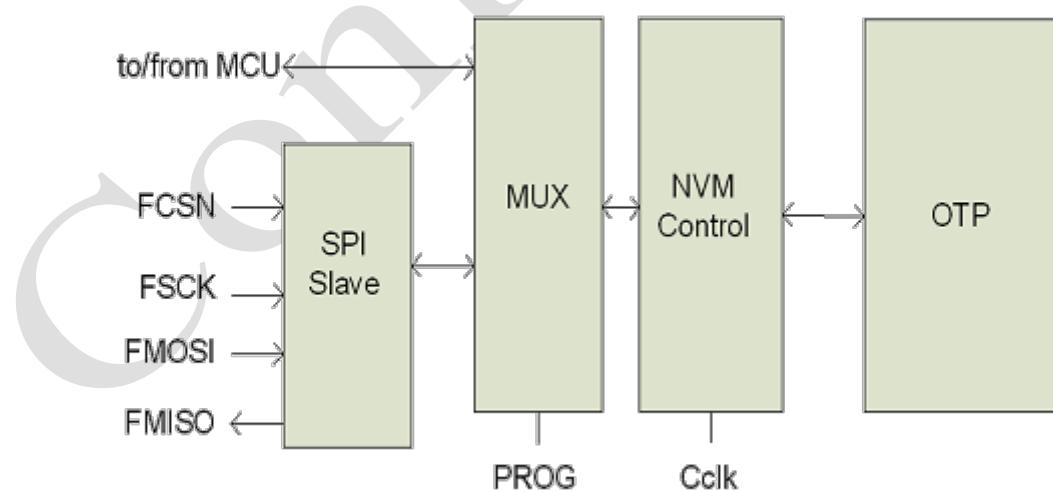

The OTP memory is configured and programmed through an external SPI slave interface. After programming, read and write operations from the external interfaces can be disabled for code protection.

6.1 Features

- 16 kB code memory
- Up to 2 kB can be mapped to data memory
- Direct SPI programmable
- Read and write protection

6.2 Block diagram

OTP is accessible by SPI slave during programming and MCU as selected by the PROG pin. A memory controller generates the necessary timing for accessing the OTP memory.

6.3 Functional description

The OTP block gives the MCU its code space for program storage and NV (not violation) memory space for storing of application data. The NV memory can be accessed by the MCU through both normal code and data space operations.

6.3.1 Using the NV data memory

By default, the 2 kB NV memory is addressed by MCU as code memory in the range of 0x3800~0x3FFF. By setting the value of MEMCON, this NV memory can be addressed as XDATA memory in the range of 0x3800~0x3FFF. This memory is physically mapped (for SPI access) to OTP memory area 0x3800–0x3FFF.

6.3.2 OTP memory configuration

6.3.2.1 OTP read and write protection

The last byte of the OTP memory which is at address 0x3FFF is used to disable read and write to the OTP from the SPI interface. This byte can be accessed by MCU and SPI interface. When this byte is:

- 0x00: OTP block is accessible from external interfaces
- Other value: No read/ write of OTP block from external interfaces

6.3.2.2 Memory status register FSR

Address	Bit	Name	Reset value	SPI	SFR	Description
0xF8	7	xosc16m_dy	0	R	R	1: xosc16m is ready, and begin to program OTP. 0: xosc16m is not ready, and wait xosc16m ready to program OTP.
	6	VRF_MO_DE	0	RW	RW	Only used in program and verify operation 1: one cycle to read(50ns OTP) 0: two cycle to read(50ns and 70ns OTP)
	5	WEN	0	RW	RW	OTP write enable latch. Enables OTP write operations from SPI or MCU.
	4	RDYN	1	R	R	OTP ready flag, active low. Before write date to OTP, you must check if OTP has been ready.
	3	prog_fail	0	R	R	1 indicate OTP program and verify process is failed
	2	RDISMB	0	R	R	OTP main block read and write protection enabled 0:ExternalSPI have full access (read and write) to the OTP. 1: External SPI do not access to the OTP.

	1	TSTSTU	0	R	R	When 1, indicate the previous TEST (Blank Check or TESTDEC) is failed.
	0	TSTEND	0	R	R	When 1, indicate the previous TEST (Blank Check or TESTDEC) is finished.

6.3.2.3 Memory Control Register – MEMCON

The MEMCON register is used to control the number of OTP memory which can be mapped into the data space of MCU.

Address	Bit	Name	Reset value	RW	Description
0xA7	7:2	-	--	--	Not used
	1:0	mc	2'b00	RW	0: no OTP is mapped in data space. 1: the upper 512 bytes ofOTP are mapped to data space. 2: the upper 1K bytes ofOTP are mapped to data space. 3: the upper 2K bytes ofOTP are mapped to data space.

6.3.3 Brown-out

There is an on-chip power-fail brown-out detector, which ensures that any OTP memory program access will be ignored when the Power Fail (POF) signal. Both the microcontroller and the OTP memory write operation still function according to specification, and any write operation that was started will be completed. The Power-fail comparator is disabled after startup and can be enabled by setting bit 7 in POFCON.

If the supply voltage drops below ~1.7V, that is when the Brown-Out Reset (BOR) signal is active, the chip will be reset. If the power supply rises again before reaching the reset threshold, there will be no reset. In order to have an indication that shows this has happened, one will need to enable the Power Failure interrupt (POFIRQ).

6.3.4 OTP programming from the MCU

This section describes how you can write the OTP memory by using the MCU.

The clock frequency of the microcontroller must be 16 MHz during OTP write operations, that bit[7] in FSR register must be 1.

To allow write OTP operations the MCU must run the following sequence:

1. Set WEN (bit 5) in the FSR high to enable OTP writing access. The OTP is now open for writing from the MCU until WEN in FSR is set low again.
2. If write to code space is intended, set PMW (bit 4) in the PCON register high to enable program memory write mode.
3. Programming the OTP is done through normal memory write operations from the MCU. Bytes are written individually (there is no

auto increment) to the OTP using the specific memory address.

When the programming code executes from the OTP, write operation is self-timed and the CPU stops until the operation is finished. If the programming code executes from the XDATA RAM the code must wait until the operation has finished. Do not set WEN low before the write operation is finished. Memory address is identical to the OTP address, see chapter 5 for memory mapping.

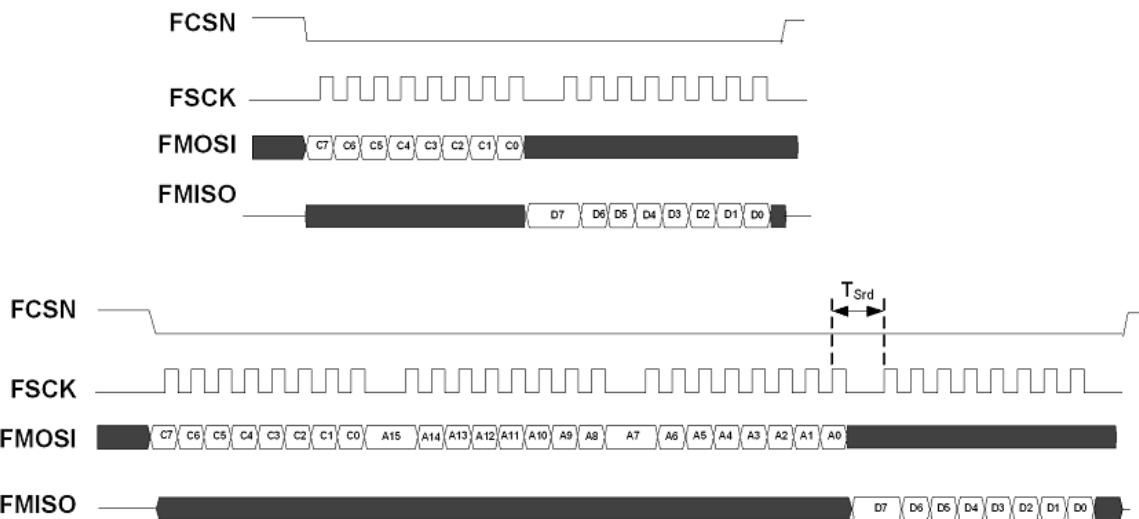

6.3.5 OTP programming through SPI

The on-chip OTP is designed to interface a standard SPI device for programming. The interface uses an 8-bit command register and a set of commands to program and configure the OTP memory. Before write and read OTP, you should check if the RDYN bit of the register FSR is low. If the RDYN bit of the register FSR isn't low, wait until it becomes low.

To program the memory the SPI slave interface is used. SPI slave connection to the OTP memory is activated by setting pin TEST = 1, P0.0 = 0,P0.1 = 0, P0.2 = 0,P0.3 = 0, while the reset pin is kept inactive. Then apply a pulse on the Prstn pin (PullPrstn pin low for a minimum of 0.2μs and return to high). The value of the pins should be kept for at least 10 us. Selected OTP GPIO pins are automatically configured as a SPI slave.

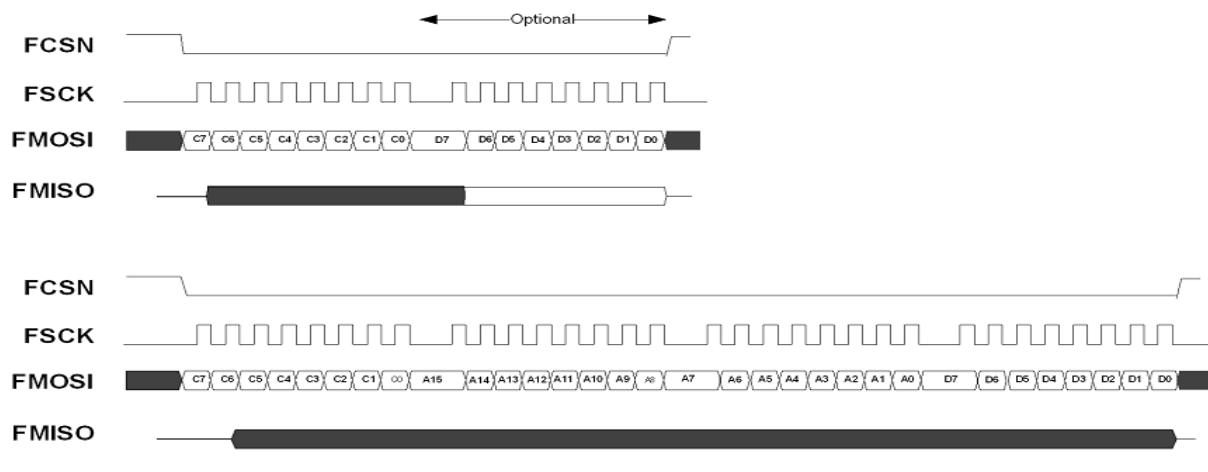

Command	Format	Address	Data	Command operation
WREN	0x06	NA	0	Set OTP write enable latch. Bit WEN in register FSR
WRDIS	0x04	NA	0	Reset OTP write enable latch. Bit WEN in register FSR
RDSR	0x05	NA	1	Read OTP Status Register (FSR)
WRSR	0x01	NA	1	Write OTP Status Register (FSR)
READ	0x03	2 bytes, first OTP address to be read	1–16384	Read data from OTP
PROGRAM	0x02	2 bytes, first OTP address to be written	1–256	Write data to OTP Note: WEN must be set.
RESET	0x80	NA	0	Reset the OTP control state
BLKCHK	0x8a	NA	0	Enable Blank Check test
TESTDEC	0x8b	NA	0	Enable TESTDEC test
SPRON	0x8c	NA	0	Enable spare bit write/read in OTP
SPROFF	0x8d	NA	0	Disable spare bit write/read in OTP

The signaling of the SPI interface is shown:

SPI read operation for direct and addressed command

Note: For the READ command there must be a delay, T_{Srd} , from the last address bit to the first data bit. Minimum value of T_{Srd} is 5 clock cycles + 10ns, which is 322.5 ns when system clock is 16MHz.

SPI write operations for direct and addressed commands

WREN / WRDIS OTP write enable/disable

SPI commands WRENand WRDISsets and resets the OTP write enable latch WEN in register FSR. This latch enables all write operations in the OTP blocks. The device will power-up in write disable state, and automatically go back to write disable state after

each write SPI command (FCSN set high). Each write command over the SPI interface must therefore be preceded by a WREN command. Both WREN and WRDIS are 1-byte SPI commands with no data.

RDSR / WRSR read/write OTP status register

SPI commands RDSR and WRSR read and write to the OTP status register FSR. Both commands are 1 and are followed by a data byte for the FSR content.

READ

SPI command READ reads out the content of an addressed position in the OTP main block. It must be followed by 2 bytes denoting the start address of the read operation. If the FCSN line is kept active after the first data byte is read out the read command can be extended, the address is auto incremented and data continues to shift out.

A read back of the OTP main block content is only possible if the read disable bit RDISMB in the FSR register is not set.

PROGRAM

SPI command PROGRAM, programs the content of the addressed position in the OTP main block. It must be followed by 2 bytes denoting the start address of the write operation. Before each write operation the write enable latch WEN must be enabled through the WREN SPI command. It is possible to write up to 256Byte in one PROGRAM command. The first byte can be at any address.

6.4 Production Test

In the following sections, the test patterns for the OTP Memory are described. The tests can be performed during wafer sort or final test or in-system/in-field depending on the test flow being used by the end user. Below each test is described.

6.4.1 Blank Check (Defective Bit Screen Test)

Blank Check enables an end user to verify that OTP memory is preloaded with “0” before actual programming. Blank Check must be performed before any other tests or any programming is performed on the OTP memory. Blank check must only be run once on OTP memory.

OTP memory technology depends on hard breakdown of gate oxide in standard logic CMOS process. It is important that integrity of gate oxide be checked before any tests or any programming is performed on OTP memory. This is done by reading every bit location at nominal VDD, nominal VDDIO and elevated VPP which ensures that defective bits caused due to defective gate oxides are screened out. If any of the bits do not read a “0”, the chip is screened out.

To do the blank check test:

- Write BLKCHK command through SPI. Then the OTP controller block will do the blank check automatically.
- Send RDSR command to read FSR register, if Bit 0 of it is 1 which indicates the test is finished. Then check the value of Bit 1. If it is 0, the blank test is passed, otherwise it is failed.
- Write RESET command to reset SPI controller.

6.4.2 TESTDEC (Word-line and Bit-line Integrity Test)

TESTDEC enables an end user to verify the integrity of word-lines and bit-lines as well as screen out the gross defects in the peripheral logic. It is performed on an un-programmed unit and is valid only for un-programmed units.

The expected test pattern is a variation of a checkerboard pattern. If the expected test pattern is not observed, the chip is screened out. The expected test patterns are shown in Table below.

Density	Program width	Read width	TESTDEC pattern		
16Kb	1	8	A<3>=0(even)	8'h00	8'hFF
			A<3>=1(odd)	8'hFF	8'h00
16Kb	1	1	A<3>=0(even)	1'b0	1'b1
			A<3>=1(odd)	1'b1	1'b0

To do the TESTDEC test:

- Write TESTDEC command through SPI. Then the OTP controller block will do the TESTDEC test automatically.
- Send RDSR command to read FSR register, if Bit 0 of it is 1 which indicates the test is finished. Then check the value of Bit 1. If it is 0, the TESTDEC test is passed, otherwise it is failed.
- Write RESET command to reset SPI controller.

6.4.3 WRTEST (Pre-program Test)

WRTEST enables an end user to screen out gross defects in programming circuitry before programming of the actual OTP memory array is done. This is enabled by the availability of two spare rows for programming.

This mode is especially useful if the end user is planning to program the OTP memory in the field or in-system since it gives an indication of program circuitry functionality before field-programming or in-system programming is done. If the user is planning to program the OTP memory array in the factory during wafer sort, then this test mode can be skipped.

Table 5 specifies the valid address ranges for the WRTEST mode during programming and during read for the various XPM memories in the 0.11um process node.

Program width	Read width	Address range during programming and during read for WRTEST mode
1	8	If A[13]=0, spare row 0 is selected; if A[13]=1, spare row 1 is selected; A[8:3] selects one of 64 8-bit words; A[12:9] and A[2:0] are don't cares.

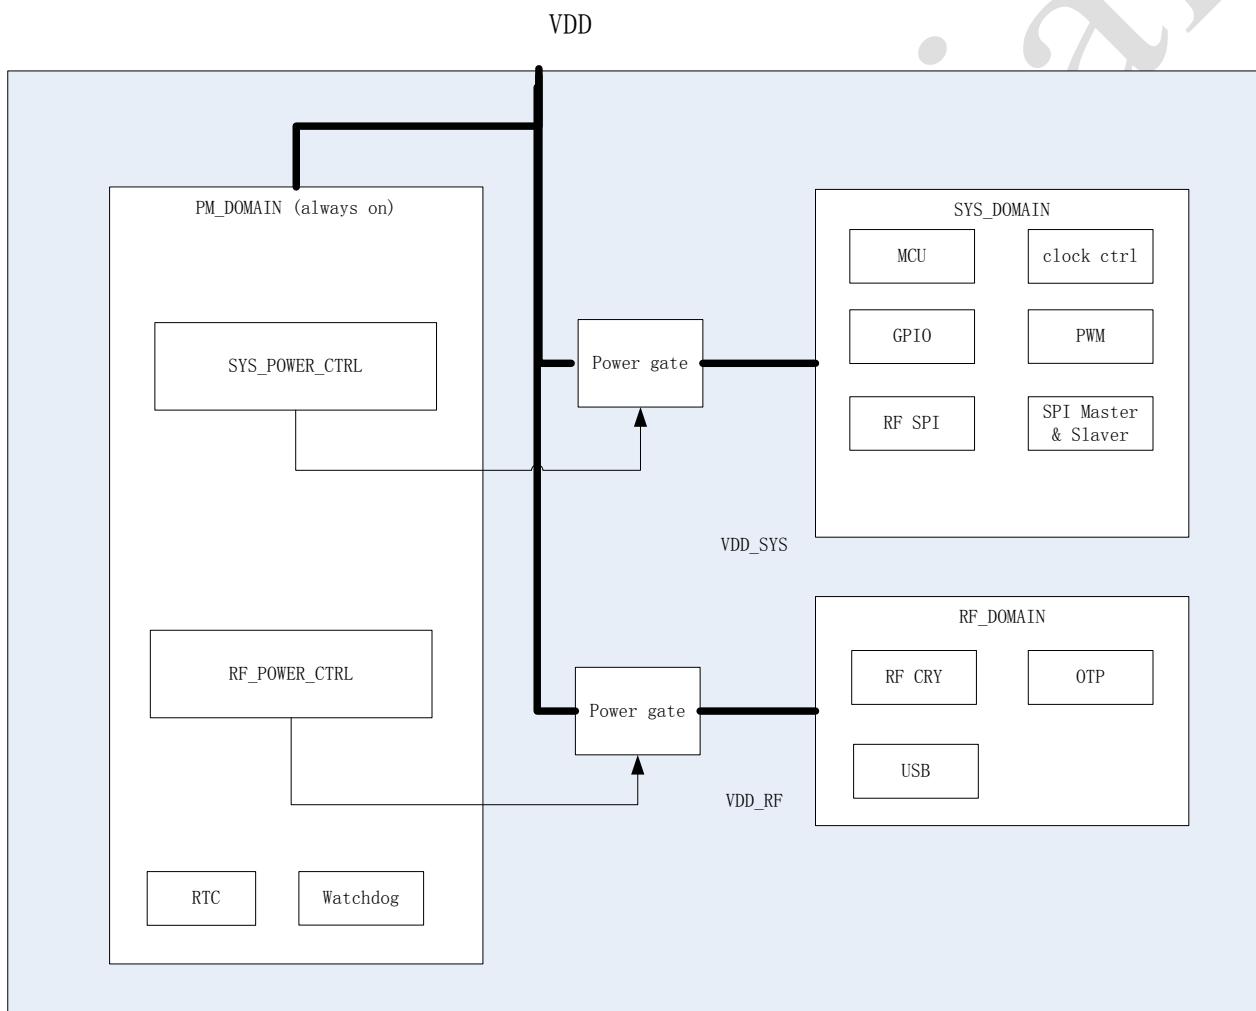

To do the WRTEST test:

- Write SPRON command through SPI to enable the spare row for writing.
- Write RESET command to reset SPI controller.
- Write WREN command to enable OTP writing.
- Write 64 byte to OTP start of address 0x0000 in spare row 0, and then wait writing process is finished by reading the OTP RDYN bit of FSR.
- Write another 64 byte to OTP start of address 0x2000 in spare row 1, and then wait writing process is finished by reading the OTP RDYN bit of FSR.
- Read the previous 128 byte data by sending READ command, if the readout values is the same as the data written into, then the WRTEST is passed.
- Write SPROFF command through SPI to disable the spare row.
- Write RESET command to reset SPI controller.

7 Power management

7.1 Power domain

There are four power domains in the chip.

PM_DOMAIN is always on when the chip is power up. When the chip is in deep sleep mode, all the other two domains include SYS_DOMAIN and RF_DOMAIN are powered down.

When the chip is in register retention mode, SYS_DOMAIN is kept power up while only RF_DOMAIN is powered down.

When the chip is in standby or active mode, all the three power domains are keep power up.

7.2 Mode of operation

After the chip is reset or powered on it enters active mode and the functional behavior is controlled by software. To enter one of the power saving modes, the PWRDWN register must be written with selected mode (as data). To re-enter the active mode a wakeup source (valid for given power down mode) has to be activated

Mode	Brief description
Deep sleep timer off	<p>Current: 0.2uA</p> <p>Powered function:</p> <ul style="list-style-type: none"> • pins inclusive wakeup filter <p>Wakeup source(s):</p> <ul style="list-style-type: none"> • From pin <p>Comment:</p> <p>Wakeup from pin will in this mode lead to a system reset (after wakeup, program execution will start from the reset vector)</p>

--------	--

7.3 Functional description

7.3.1 Power down control – PWRDWN

The PWRDWN register is used by the MCU to set the system to a power saving mode:

Address	Bit	Reset value	R/W	Description
0xA4	7	1'b0	R	Indicates a wakeup from pin if set This bit is cleared by entering a power down mode
	6	1'b0	R	Indicates a wakeup from TICK if set This bit is cleared by entering a power down mode
	5	1'b0	R	0: indicates WUIRQ is a wakeup interrupt, if IEN1[5]=1(wakeup from standby mode to active mode) 1: indicates WUIRQ is a RTC timer interrupt, if IEN1[5]=1(active mode)
	4			Reserved
	3	1'b0	RW	1:enable USB 0:disable USB(default)

	2:0	3'b0	W	Set system to power down if different from 000 001: set system to DeepSleep 010: reserved 011: reserved 100: set system to Register retention 101: reserved 110: reserved 111: set system to standby (stop MCU clock) Shows previous power down mode 000: Power off 001: DeepSleep 010: reserved 011: reserved 100: Register retention 101: reserved 110: reserved 111: standby
--	-----	------	---	---

7.3.2 Power Fail register- POFCON

Address	Bit	Name	Reset value	RW	Description
0xDC	7	pof_en	1'b0	RW	POF enable, high active
	6:4	pof_thr	3'b000	RW	If power is lower than pofthreshold, pof_warn will be active 000: 1.0V 001: 1.2V 010: 1.4V 011: 1.8V 100: 2.0V 101: 2.2V 110: 2.4V 111: 2.7V
	3	pof_warn	1'b1	R	power fail warning, low active; output 1 when pof disable
	2:1	bor_thr	2'b00	RW	If power is lower than borthreshold, system reset will be active. 00: the threshold is 1.7V 01: the threshold is 1.75V 10: the threshold is 1.8V 11: the threshold is 1.85V
	0	---	1'b0	--	Not used

7.3.3 Reset result – RSTREAS

There are four reset sources that initiate the same reset/ start-up sequence. These are:

- Reset from the on chip reset generator
- Reset from pin
- Reset generated from the on chip watchdog function

The RSTREAS register stores the reason for the last reset, all cleared indicates that the last reset was from the on-chip reset generator. A write operation to the register will clear all bits. Unless cleared after read (by on-chip reset or by a write operation), RSTREAS will be cumulative.

Address	Bit	Reset value	R/W	Description
0xB1	7		-	Not used
	6		W	Writing 1 to reset PWM module
	5		W	Writing 1 to reset RF SPI master module
	4		W	Writing 1 to reset SPI slaver module
	3		W	Writing 1 to reset SPI master module
	2		W	Writing 1 to reset 32k osc calibration module
	1:0	2'b0	R	00: On-chip reset generator 01: RST pin 10: Watchdog

7.3.4 Wakeup configuration register – WUCON

The following wakeup sources are available in STANDBY power down mode.

Address	Bit	Reset value	R/W	Description
0xA5	7:6	2'b0	RW	00: Enable wakeup on RFIRQ if interrupt is enabled (IEN1.1=1) 01: Reserved, not used 10: Enable wakeup on RFIRQ 11: Ignore RFIRQ
	5:4	2'b0	RW	00: Enable wakeup on WU, if IEN1[5]=1 01: Reserved, not used 10: Enable wakeup on WU, regardless of IEN1[5] 11: Ignore WU

	3:2	2'b0	RW	00: Enable wakeup on USBIRQ, if IEN1[4]=1 01: Reserved, not used 10: Enable wakeup on USBIRQ, regardless of EN1 [4] 11: Ignore USBIRQ
	1:0	2'b0	RW	00: Enable wakeup on USBWU, if IEN1[3]=1 01: Reserved, not used 10: Enable wakeup on USBWU, regardless of IEN1[3] 11: Ignore USBWU

7.3.5 Mode Control – OPMCON

It is used to control the delay time which is required in power up sequence.

Default: 0xC5

Address	Bit	Reset value	R/W	Description
0xAE	7:6	2'b11	RW	The time is requited for 3.3V charge pump power up before system start working. 2'b00: 500us 2'b01: 1ms 2'b10: 2ms 2'b11: 3ms
	5:4		-	Reserved
	3:2	2'b01	RW	The time is required for waiting after system power domain power up 2'b00 : not waiting 2'b01: 80 16M clock cycles 2'b10: 160 16M clock cycles 2'b11: 255 16M clock cycle
	1:0	2'b01	RW	The time is required for waiting after RF power domain power up 2'b00 : not waiting 2'b01: 80 16M clock cycles 2'b10: 160 16M clock cycles 2'b11: 255 16M clock cycle

7.3.6 Charge pump and 2v LDO for sensor register–CPLDOCON

Address	Bit	Reset value	R/W	Description
0xF4	7:1	7'h00	--	Reserved
	0	1'b0	RW	2v ldo power down

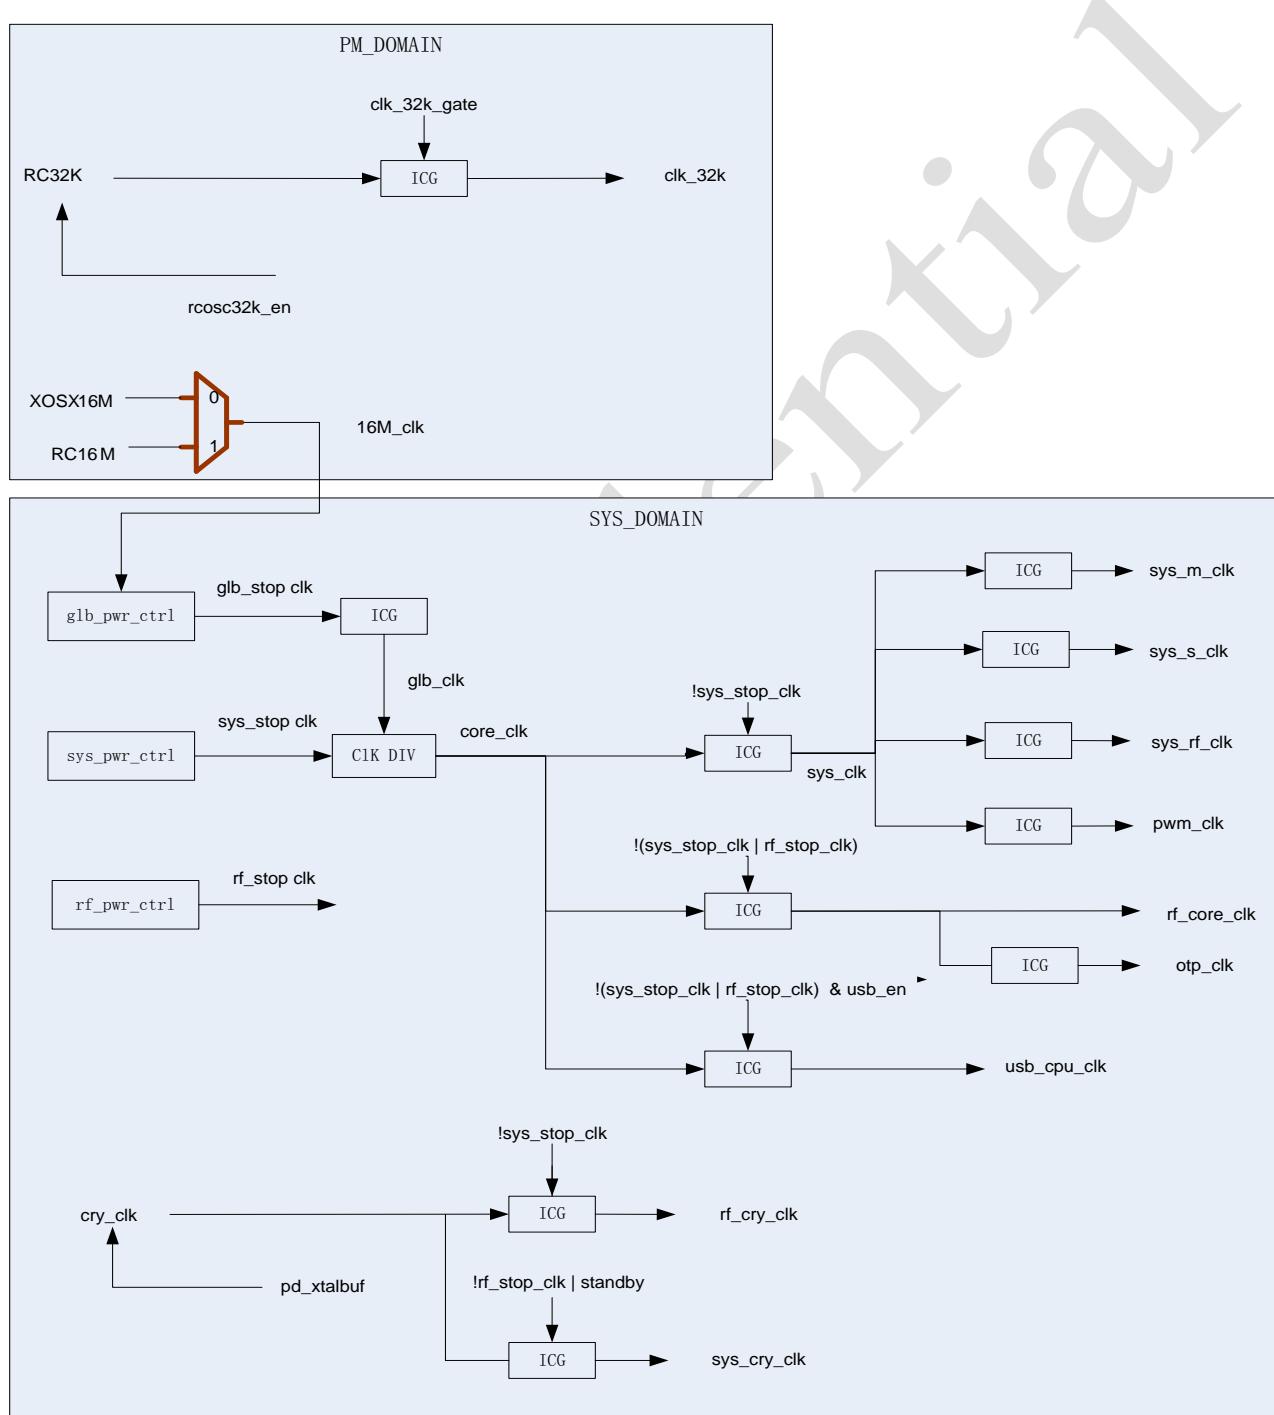

7.4 Power consumption

Condition: temperature =+25

Module	digital	analog
Deep sleep (RTC off)	0.5uA	0.8uA
Deep sleep (RTC on)	0.8uA	2.8uA
Register retention (RTC off)	10.0uA	0.8uA
Register retention (RTC on with RC 32K)	10.3uA	2.8uA
Standby (RTC on with 1M clock from osc16M)	205uA	360uA

8 Clock and Reset management

8.1 Clock Block diagram

8.2 Clock control

The source and frequency of the clock to the microcontroller system is controlled by the CLKCTRL register. Because the read data delay of OTP memory is maximum 70ns, when the microcontroller system clock is 16MHz, the program memory wait cycle defined in register CKCON bit [6:4] should be at least 1, otherwise the system will be failed.

Address	Bit	Reset value	R/W	Description
0xA3	7:5	3'b0	RW	Clock frequency to debounce block: 000: 16 MHz 001: 8 MHz 010: 4 MHz 011: 2 MHz 100: 1 MHz 101: 500 kHz 110: 250 kHz 111: 125 kHz
	4		R	When 1 indicates the XOSC 16M clock is enable
	3	1'b0	RW	1: Enable wakeup and interrupt (X16IRQ) from XOSC16M active 0: Disable wakeup and interrupt from XOSC16M active
	2:0	3'b0	RW	Clock frequency to microcontroller system: 000: 16 MHz 001: 8 MHz 010: 4 MHz 011: 2 MHz 100: 1 MHz 101: 500 kHz 110: 250 kHz 111: 125 kHz

Each module can be clock gated by CLKGATE register

Address	Bit	Reset value	R/W	Description
0xAC	7	1'b0	RW	1: Keep LDO on in sleep mode 0: Gate LDO in sleep mode(default) Note: in standby mode this bit must be set as 1
	6	1'b0	RW	1: Keep XOSC16M on in sleep mode 0: Gate XOSC16Min sleepmode(default) Note: in standby mode this bit is ignored, andXOSC16M is always on.

	5	1'b0	RW	1 enable debounce block
	4	1'b1	RW	Clock enable for SPI master
	3	1'b1	RW	Clock enable for SPI slaver
	2	1'b1	RW	Clock enable for RF SPI
	1	1'b1	RW	Clock enable for 16MHz clock which used in PWM and OSC calibration block
	0	1'b1	RW	Clock enable for OTP controller, program still can be read by MCU even when OTP clock is gated

8.3 32K OSC clock calibration

The source of the 32 kHz clock is controlled by the CLKLFCTRL register. 32k OSC clock calibration must be done when the frequency of system clock is 16MHz.

Address	Bit	Reset value	R/W	Description
0xAD	7		R	Read CLKLF (phase).
	6:5	2'b00	RW	Source for CLKLF: 00: RCOSC32K 01:32K generated from XOSC16M when active, off otherwise ^a 10:1M generated from XOSC16M when active, off otherwise ^a 11:4M generated from XOSC16M when active, off otherwise ^a
	4		R	When 1 indicates osc32kcalibration is done
	3	1'b0	RW	Write 1 to start osc32k calibration.
	2		R	After changing the source of the CLKLF by setting bit[6:5], the changing process is finished when read 1 from this bit.
	1	1'b1	RW	Internal 32 kHz clock gating is enable when 1.
	0	1'b0	RW	Enable the 32 kHz clock

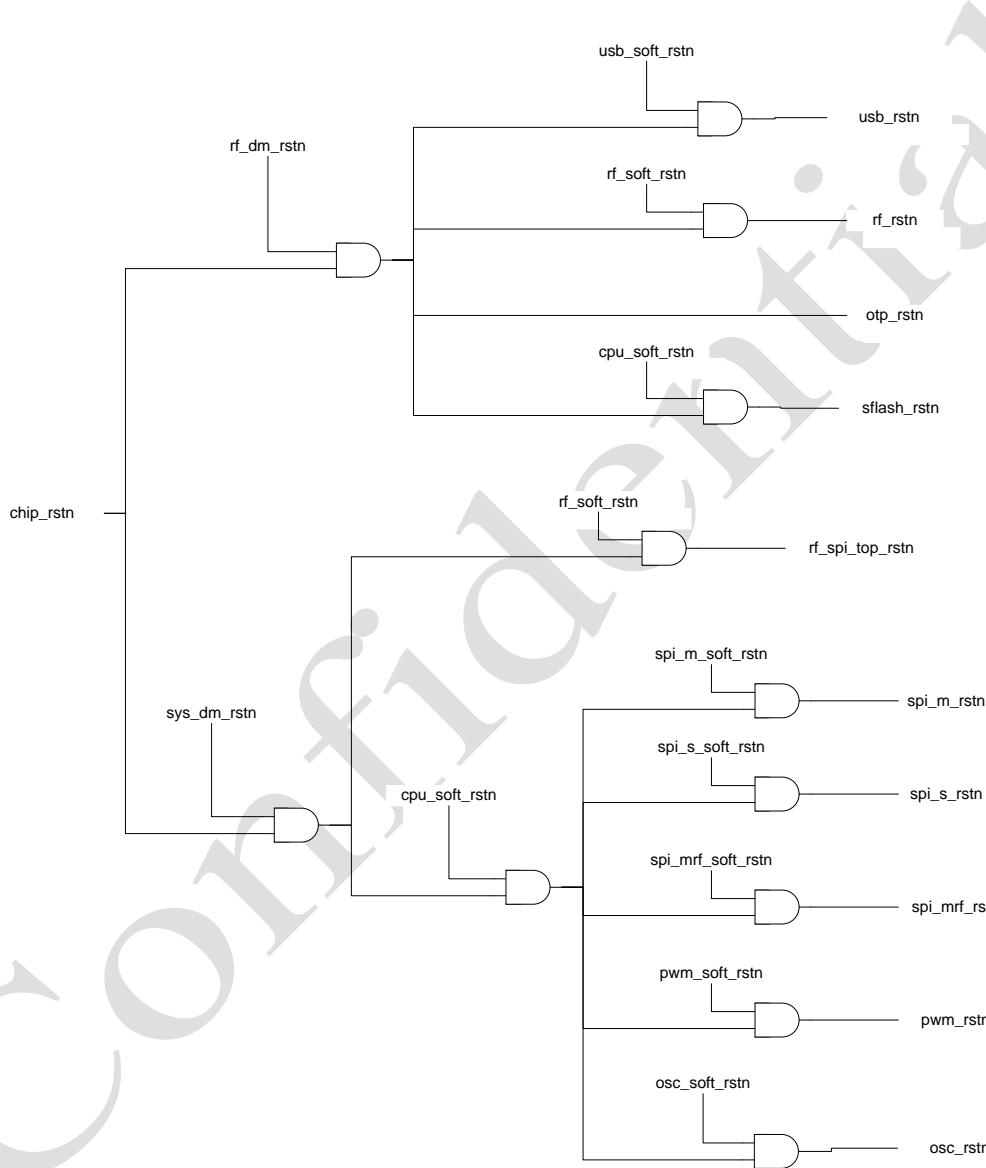

a: In default XOSC16M will be stopped in Deep Sleep and Register Retention mode. If the CLKLF is required to be sourced from XOSC16M in Register Retention mode, bit 6 of the CLKGATE register should be kept as 1.

The status of the OSC calibration is controlled by OSC_CTL register:

Address	Bit	Reset value	R/W	Description
0xAF	7:3	5'b0	RW	osc32k control manual value.
	2	1'b0	RW	1: osc32k_ctrl come fromregister; 0: osc32k_ctrl come from FSM
	1	1'b0	RW	osc32k_cal_en manual value.
	0	1'b0	RW	1: osc32k_cal_en come from register;0:osc32k_cal_en come from FSM

8.4 Reset Control

The block diagram for reset controller is:

The chip reset is a combination of power reset (porb), pin reset (prstn) and watch dog reset. Signal rf_dm_rstn and sys_dm_rstn are controlled by the power controller. Usb_soft_rstn is USB software reset controlled by the USB internal register (USBCON). Rf_soft_rstn is RF software reset controlled by RF internal register. Cpu_soft_rstn is a system software reset controlled by register SRST. Other control signals are software reset for other peripherals controlled by register RSTREA.

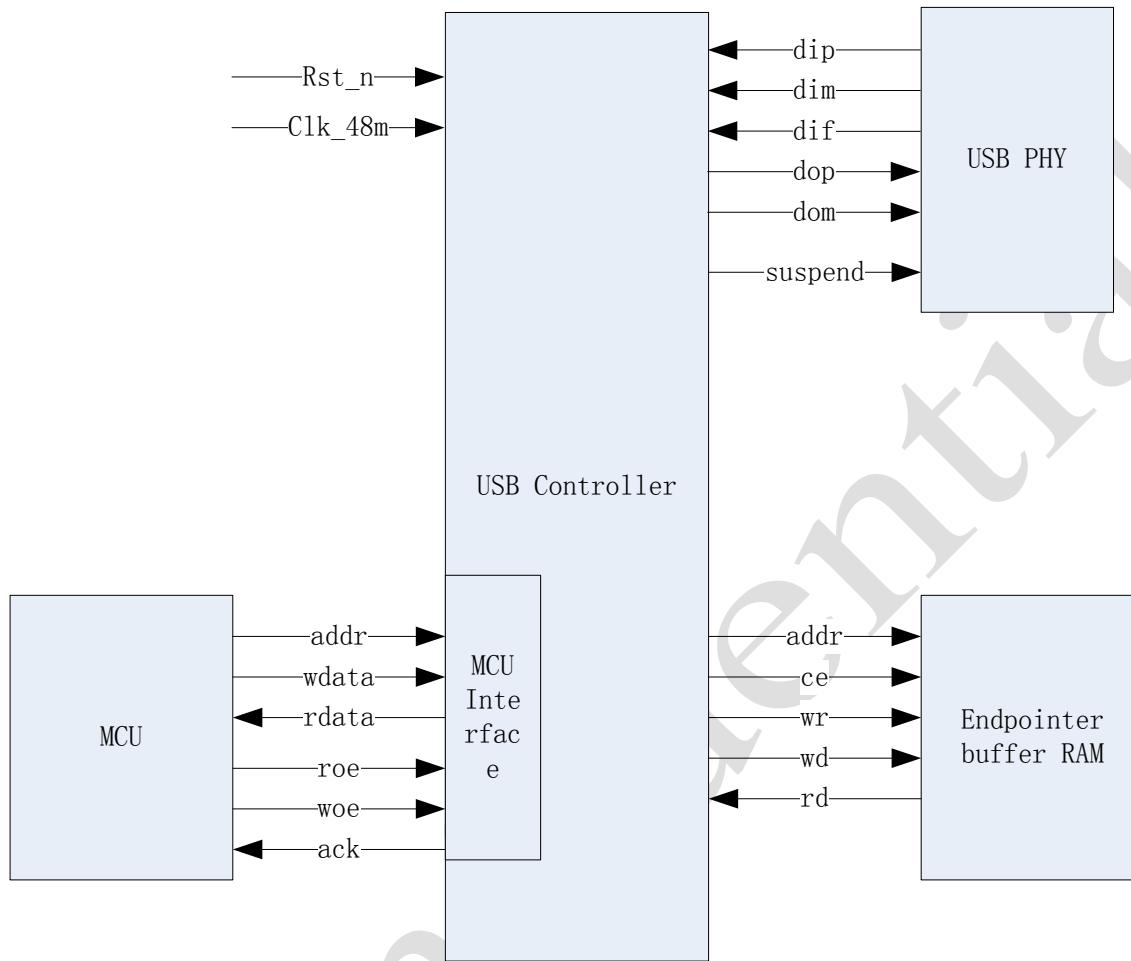

9 USB Configuration

The USB device controller is compatible with USB 2.0 Full-speed(12 Mbps) function.

9.1 Feature

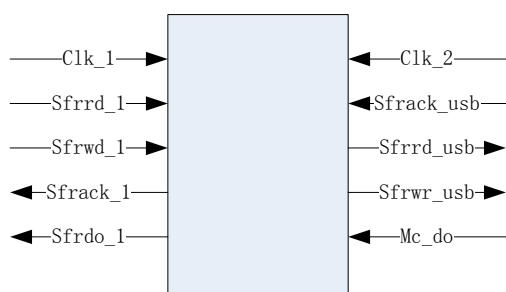

- Conforms to 1.1 and 2.0 revision of the USB specification.
- Support 8 endpoints (include endpoint 0).
- Each endpoint have 16 bytes IN buffer and 16 bytes OUT buffer
- Serial Interface Engine
 - Supports full speed devices
 - NRZI decoding/encoding
 - Bit stuffing/stripping
 - CRC checking/generation
 - On-chip pull-up resistorwith software controlled disconnect
- Automatic data retry mechanism
- Data toggle synchronization mechanism
- Suspend and resume power management functions
- Remote Wakeup function

9.2 Block diagram

9.3 MCU interface

The USB controller host interface is work at 12M. The MCU clock is asynchronous to the USB host interface so there is a MCU interface to transfer the MCU cycle to the USB.

9.4 Wakeup/suspend control

If the USB has not find activity on the USB for 3ms, it will generate a Suspend interrupt (if enabled). It is up to the software to decide what, if anything, to disable when the USB is in Suspend mode. The USB 48M PLL will stop. When USB detect Resume signaling (by monitoring the DIM and DIP signals) it will enable the 48M PLL and generate Resume interrupt. The en_48M will manual turn the 48M PLL on.

If the USB is in Suspend mode and the software wants to initiate a remote wakeup, it should write to the sw_wu to enable the 48M PLL. It will take 100us to let the PLL stable then software need to set the Resume bit (D2) in Power register to 1. The software should leave this bit set for approximately 10ms (minimum of 2ms, a maximum of 15ms) then reset it to 0. By this time the hub should have taken over driving Resume signaling on the USB. The sw_wu must be clear before USB goes into the suspend mode otherwise the 48M PLL will not stop.

Note: No Resume interrupt will be generated when the software initiates a remote wakeup.

9.5 SFR register

9.6 USB Registers

Note: In the following bit descriptions:

- ‘R’ means that the bit is read only
 - ‘RW’ means that the bit can be both read and written
 - ‘Set’ means that the bit can only be written to set it
 - ‘R/Set’ means that the bit can be read or set but it can’t be cleared
 - ‘Clear’ means that the bit can only be written to clear it
 - ‘R/Clear’ means that the bit can be read or cleared but it can’t be set
 - ‘Self-clearing’ means the bit will be cleared automatically when the associated action has been executed.

9.6.1 Function address register– FADDR

FAddr is an 8-bit register that should be written with the function's 7-bit address. It is then used for decoding the function address in subsequent token packets.

FADDR (RW)

0xC000

Description of Word

Bit	Value	Symbol	Description
7	1'b0	Update	Set when FAddr is written. Cleared when the new address takes effect (at the end of the current transfer).
6:0	7'h0	FAddr	The function address.

9.6.2 Power management register-POWER

POWER (RW) 0xC001

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit0
ISO Update	---			Reset	Resume	SuspendMode	EnableSuspend
1'b0	3'b000			1'b0	1'b0	1'b0	1'b0
RW	R			R	RW	R	RW

Description of Word

Bit	Value	Symbol	Description
7	1'b0	ISO Update	When set by the CPU the MUSBFSFC will wait for an SOF token from the time InPktRdy is set before sending the packet. If an IN token is received before an SOF token, then a zero length datapacket will be sent. This bit is only used by endpoints performing Isochronous transfers.
6:4	3'b000	---	Unused, always return zero.
3	1'b0	Reset	This read only bit is set while Reset signaling is present on the bus.
2	1'b0	Resume	Set by the CPU to generate Resume signaling when the function is in Suspend mode. The CPU should clear this bit after 10ms (a maximum of 15ms) to end Resume signaling.
1	1'b0	SuspendMode	Set by the USB when Suspend mode is entered. Cleared when the CPU reads the interrupt register, or sets the Resume bit of this register.
0	1'b0	EnableSuspend	Set by the CPU to enable entry into Suspend mode when Suspend signaling is received on the bus.

9.6.3 Interrupt register for Endpoint 0 plus IN Endpoints 1 to 7-INTRIN1

IntrIn1 is an 8-bit read-only register that indicates which of the interrupts for IN Endpoints 1–7 are currently active. It also indicates whether the Endpoint 0 interrupt is currently active. Note: All active interrupts will be cleared when this register is read.

INTRIN1 (R) 0xC002

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit0
EP7	EP6	EP5	EP4	EP3	EP2	EP1	EP0
1'b0	1'b0						
R	R	R	R	R	R	R	R

Description of Word

Bit	Value	Symbol	Description
7	1'b0	EP7	IN Endpoint 7 interrupt.
6	1'b0	EP6	IN Endpoint 6 interrupt.
5	1'b0	EP5	IN Endpoint 5 interrupt.
4	1'b0	EP4	IN Endpoint 4 interrupt.
3	1'b0	EP3	IN Endpoint 3 interrupt.
2	1'b0	EP2	IN Endpoint 2 interrupt.
1	1'b0	EP1	IN Endpoint 1 interrupt.
0	1'b0	EP0	IN Endpoint 0 interrupt.

9.6.4 Interrupt register for IN Endpoints 8 to 15-INTRIN2

IntrIn2 is an 8-bit read-only register that indicates which of the interrupts for IN Endpoints 8–15 are currently active. This register will only be present if the MUSBFSFC is configured for more than 7 IN endpoints. Note: All active interrupts will be cleared when this register is read.

9.6.15 Index register for selecting the endpoint status and control registers-INDEX

Index is a 4-bit register that determines which endpoint control/status registers are accessed at addresses 0xC010h to 0xC017h. Each IN endpoint and each OUT endpoint have their own set of control/status registers. Only one set of IN control/status and one set of OUT control/status registers appear in the memory map at any one time. Before accessing an endpoint's control/status registers, the endpoint number should be written to the Index register to ensure that the correct control/status registers appear in the memory map.

INDEX (RW)

0xC00E

Bit 3	Bit 2	Bit 1	Bit 0

3:0	4'b0000	Index	Selected Endpoint.

9.6.16 Control Status register for Endpoint 0-CSR0

CSR0 is an 8-bit register that provides control and status bits for Endpoint 0. CSR0 is used for all control/status of Endpoint0.

CSR0

0xC011

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Serviced SetupEnd (self-clearing)	Serviced OutPktRdy (self-clearing)	SendStall (self-clearing)	SendStall (self-clearing)	DataEnd (self-clearing)	SentStall	InPktRdy (self-clearing)	OutPktRdy
1'b0	1'b0	1'b0	1'b0	1'b0	1'b0	1'b0	1'b0
Set	Set	Set	R	Set	R/Clear	R/Set	R

Description of Word

Bit	Value	Symbol	Description
-----	-------	--------	-------------

7	1'b0	ServicedSetupEnd	The CPU writes a 1 to this bit to clear the SetupEnd bit. It is cleared automatically.
6	1'b0	ServicedOutPktRdy	The CPU writes a 1 to this bit to clear the OutPktRdy bit. It is cleared automatically.
5	1'b0	SendStall	The CPU writes a 1 to this bit to terminate the current transaction. The STALL handshake will be transmitted and then this bit will be cleared automatically.
4	1'b0	SendStall	This bit will be set when a control transaction ends before the DataEnd bit has been set. An interrupt will be generated and the FIFO flushed at this time. The bit is cleared by the CPU writing a 1 to the ServicedSetupEnd bit.
3	1'b0	DataEnd	The CPU sets this bit: 1. When setting InPktRdy for the last data packet. 2. When clearing OutPktRdy after unloading the last data packet. 3. When setting InPktRdy for a zero length data packet. It is cleared automatically.
2	1'b0	SentStall	This bit is set when a STALL handshake is transmitted. The CPU should clear this bit.
1	1'b0	InPktRdy	The CPU sets this bit after loading a data packet into the FIFO. It is cleared automatically when the data packet has been transmitted. An interrupt is generated when the bit is cleared.
0	1'b0	OutPktRdy	This bit is set when a data packet has been received. An interrupt is generated when this bit is set. The CPU clears this bit by setting the ServicedOutPktRdy bit.

9.6.17 Maximum packet size for IN endpoint-INMAXP

InMaxP is an 8-bit register that holds the maximum packet size for transactions through the currently-selected IN endpoint – in units of 8 bytes, except that a value of 2 sets the maximum packet size to 16. In setting this value, you should note the constraints placed by the USB Specification on packet sizes for Bulk, Interrupt and Isochronous transactions in Full-speed operations.

There is an InMaxP register for each IN endpoint (except Endpoint 0).

INMAXP (RW)

0xC010

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Inmaxp							
8'h00							
RW							

Description of Word

Bit	Value	Symbol	Description
7:0	8'h00	Inmaxp	Maximum Packet Size/transaction.

9.6.18 Control Status register 1 for IN endpoint-INCSR1

InCSR1 is an 8-bit register that provides control and status bits for IN transactions through the currently-selected endpoint. There is an InCSR1 register for each IN endpoint (not including Endpoint 0).

INCSR1 0xC011

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit0
---	ClrDataTog	SentStall	SendStall	FlushFIFO (self-clearing)	UnderRun	FIFO NotEmpty	InPktRdy
1'b0	1'b0	1'b0	1'b0	1'b0	1'b0	1'b0	1'b0
R	Set	R/Clear	RW	Set	R/Clear	R/Clear	R/Set

Description of Word

Bit	Value	Symbol	Description
7	1'b0	---	Unused. Returns zero when read.
6	1'b0	ClrDataTog	The CPU writes a 1 to this bit to reset the endpoint IN data toggle to 0.
5	1'b0	SentStall	This bit is set when a STALL handshake is transmitted. The FIFO is flushed and the InPktRdy bit is cleared (see below). The CPU should clear this bit.
4	1'b0	SendStall	The CPU writes a 1 to this bit to issue a STALL handshake to an IN token. The CPU clears this bit to terminate the stall condition. This bit has no effect if the IN endpoint is in ISO mode.
3	1'b0	FlushFIFO	The CPU writes a 1 to this bit to flush the next packet to be transmitted from the endpoint INFIFO. The FIFO pointer is reset and the InPktRdy bit (below) is cleared. Note: If the FIFO contains two packets, FlushFIFO will need to be set twice to completely clear the FIFO.
2	1'b0	UnderRun	In ISO mode, this bit is set when a zero length data packet is sent after receiving an IN token with the InPktRdy bit not set. In Bulk/Interrupt mode, this bit is set when a NAK is returned in response to an IN token. The CPU should clear this bit.
1	1'b0	FIFONotEmpty	This bit is set when there is at least 1 packet in the IN FIFO.
0	1'b0	InPktRdy	The CPU sets this bit after loading a data packet into the FIFO. It is cleared automatically when a data packet has been transmitted. An interrupt is generated (if enabled) when the bit is cleared.

9.6.19 Control Status register 2 for IN endpoint-INCSR2

INCSR2 is an 8-bit register that provides further control bits for IN transactions through the currently-selected endpoint. There is an InCSR2 register for each IN endpoint (not including Endpoint 0).

INCSR2

0xC012

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit0
AutoSet	ISO	Mode	DMAEnab	FrcDataTog	---	---	---
1'b0	1'b0	1'b0	1'b0	1'b0	1'b0	1'b0	1'b0
RW	RW	RW	RW	RW	R	R	R

Description of Word

Bit	Value	Symbol	Description
7	1'b0	AutoSet	If the CPU sets this bit, InPktRdy will be automatically set when data of the maximum packet size(value in InMaxP) is loaded into the IN FIFO. If a packet of less than the maximum packet size isloaded, then InPktRdy will have to be set manually.
6	1'b0	ISO	The CPU sets this bit to enable the IN endpoint for isochronous transfers (ISO mode), and clears it to enable the IN endpoint for bulk/interrupt transfers.
5	1'b0	Mode	The CPU sets this bit to enable the endpoint direction as IN, and clears it to enable the endpointdirection as OUT. Valid only where the same endpoint FIFO is used for both IN and OUT transactions.
4	1'b0	DMAEnab	The CPU sets this bit to enable the DMA request for the IN endpoint.
3	1'b0	FrcDataTog	The CPU sets this bit to force the endpoint's IN data toggle to switch after each data packet is sentregardless of whether an ACK was received. This can be used by interrupt IN endpoints which areused to communicate rate feedback for Isochronous endpoints.
2:0	3'b000	---	Unused, always return 0.

9.6.20 Maximum packet size for OUT endpoint-OUTMAXP

OutMaxP is an 8-bit register that holds the maximum packet size for transactions through the currently-selected OUT endpoint—in units of 8 bytes, except that a value of 2 sets the maximum packet size to 16. In setting this value, you should note the constraints placed by the USB Specification on packet sizes for Bulk, Interrupt and Isochronous transactions in Full-speed operations.

There is an OutMaxP register for each OUT endpoint (except Endpoint 0).

OUTMAXP (RW)

0xC013

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Outmaxp

Set	R/Clear	RW	Set	R	R/Clear	R	R/Clear

Description of Word

Bit	Value	Symbol	Description
7	1'b0	ClrDataTog	The CPU writes a 1 to this bit to reset the endpoint data toggle to 0.
6	1'b0	SentStall	This bit is set when a STALL handshake is transmitted. The CPU should clear this bit.
5	1'b0	SendStall	The CPU writes a 1 to this bit to issue a STALL handshake. The CPU clears this bit to terminate the stall condition. This bit has no effect if the OUT endpoint is in ISO mode.
4	1'b0	FlushFIFO	The CPU writes a 1 to this bit to flush the next packet to be read from the endpoint OUT FIFO. Note: If the FIFO contains two packets, FlushFIFO will need to be set twice to completely clear the FIFO.
3	1'b0	DataError	This bit is set when OutPktRdy is set if the data packet has a CRC or bit-stuff error. It is cleared when OutPktRdy is cleared. The bit is only valid in ISO mode.
2	1'b0	UnderRun	This bit is set if an OUT packet cannot be loaded into the OUT FIFO. The CPU should clear this bit. The bit is only valid in ISO mode.
1	1'b0	FIFOfull	This bit is set when no more packets can be loaded into the OUT FIFO.
0	1'b0	OutPktRdy	This bit is set when a data packet has been received. The CPU should clear this bit when the packet has been unloaded from the OUT FIFO. An interrupt is generated when the bit is set.

9.6.22 Control Status register 2 for OUT endpoint-OUTCSR2

OutCSR2 is an 8-bit register that provides further control bits for OUT transactions through the currently-selected endpoint. It is reset to 0.

OUTCSR2

0xC015

9.6.26 FIFOs for Endpoints 0 to 3-FIFOx

(Addresses 0xC020–0xC023)

This address range provides 4 addresses for CPU access to the FIFOs for each endpoint. Writing to these addresses loads data into the

HS6206

IN FIFO for the corresponding endpoint. Reading from these addresses unloads data from the OUT FIFO for the corresponding endpoint.

The FIFOs are located on byte boundaries (Endpoint 0 at 0xC020, Endpoint 1 at 0xC021 ... Endpoint 3 at 0xC023).

Confidential

10 SPI

The HS6206 features Serial Peripheral Interface (SPI), including a double-buffered SPI Master and a SPI Slave. It can be configured to work in all four SPI modes. The default is mode 0. The SPI connects to the following pins of the device: MMISO, MMOSI, MSCK, MCSN, SMISO, SMOSI, SSCK, and SCSN. And this SPI master function support 4-wire, 3-wire with MCSN (MMOSI is in-out port), 3-wire without MCSN (default mode), and 2-wire mode (MMOSI is in-out port, without MCSN).

10.1 Features

- SPI Master support double buffered FIFO
- Full-duplex operation
- Supports SPI modes 0 through 3
- SPI Master support 2-wire, 3-wire and 4wire operation modes
- SPI Master configured MMOSI to bi-directional port at 2-wire and 3-wire modes
- Configurable data order on xMISO/xMOSI

10.2 Block diagram

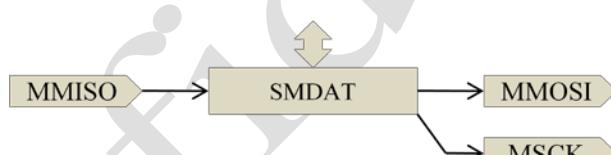

Fig. 10.1 SPI Mater

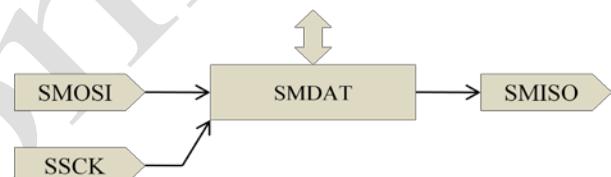

Fig. 10.2 SPI Slave

10.3 Functional description

10.3.1 SPI master

The following registers control the SPI master:

Address (Hex)	Name/mnemonic	Bit	Reset Value	Type	Description
0xFC	SPIMCON0	7:0	0x00	R/W	SPI Master configuration register0
	Spi_3wire_mode_en	7	0	R/W	1'b0: disable SPI Master 3-wire mode 1'b1: 3-wire SPI mode enable (SCK, CSN and SDIO, setting mosi_out_en bit)
	Clock frequency	6:4	000	R/W	Frequency on MSCK. ckMCU is MCU clock frequency 000: 1/2 ckMCU 001: 1/4 ckMCU 010: 1/8 ckMCU 011: 1/16 ckMCU 100: 1/32 ckMCU 101: 1/64 ckMCU 110: 1/64 ckMCU 111: 1/64 ckMCU
	Dataorder	3	0	R/W	Data order (bit wise per byte) on serial output and input (MMOSI and MMISO respectively). 1: LSBit first, MSBit last. 0: MSBit first, LSBit last.
	Clockpolarity	2	0	R/W	Defines the SPI Master's operating mode together with SPIMCON0 1: MSCK is active 'low'. 0: MSCK is active 'high'.
	Clockphase	1	0	R/W	Defines the SPI Master's operating mode together with SPIMCON0 1: Sample on trailing edge of MSCK, shift on leading edge. 0: Sample on leading edge of MSCK, shift on trailing edge.
	Spi_en	0	0	R/W	1: SPI Master is enabled. 0: SPI Master is disabled.
0xFD	SPIMCON1	7:0	0x04	R/W	SPI Master configuration register1
	Resync_en	7	0	W	When enable spi_2wire_mode, write this bit toggle the MSCK line from un-activity level to activity level for at least Tresync period, SPI_RESYNC_DLY register decide time of duration, example Fig.10.4.
	Spi_2wire_mode_en	6	0	R/W	1'b0: disable 2-wire mode. 1'b1: enable 2-wire mode.

					(SCK and SDIO, setting mosi_out_en bit)
	Csn_enable	5	0	R/W	1'b0: disable SPI Master MCSN. 1'b1: enable SPI Master MCSN.
	burst	4	0	R/W	1'b0: disable SPI Master burst, 1'b1: enable SPI Master burst, When setting this bit for SPI continuous transfer more than 1 byte or more, stop burst transfer, setting this bit to "0" before the transfer last bytes. Burst function used for these modes with MCSN.
	Mosi_flag	3	0	R	Mosi port status flag: 1: mosi - input 0: mosi - output
	Reserved	2	0	R	
	Re_trans_en	1	0	R/W	Only using 2-wire mode, if the device get out of synchronous, after wait some time re-synchronous mode, setting this bit, the devices can operation, again
	Mosi_out_en	0	0	R/W	1'b0: mosi is output 1'b1: mosi is input (only using 2-wire mode and 3-wire mode with CSN)
0xFE	SPIMSTAT	7:0	0x3F	R	SPI Mater status register
	Rxfifo_full	7	0	R	1: RX FIFO full. 0: RX FIFO can accept more data from SPI.
	Rxdata_ready	6	0	R	1: Data available in RX FIFO. 0: No data in RX FIFO.
	Txfifo_empty	5	1	R	1: TX FIFO empty. 0: Data in TX FIFO.
	Txfifo_ready	4	1	R	1: Location available in TX FIFO. 0: TX FIFO full.
	maskIrqRx_fifoFull	3	1	R/W	1: Disable interrupt when RX FIFO is full. 0: Enable interrupt when RX FIFO is full.
	maskIrqRxDataReady	2	1	R/W	1: Disable interrupt when data is available in RX FIFO. 0: Enable interrupt when data is available in RX FIFO.
	maskIrqTx_fifoEmpty	1	1	R/W	1: Disable interrupt when TX FIFO is empty. 0: Enable interrupt when TX FIFO is empty.
	maskIrqTx_fifoReady	0	1	R/W	1: Disable interrupt when a location is available in TX FIFO. 0: Enable interrupt when a location is available in TX FIFO.
0xFF	SPIMDAT	7:0	0x00	R/W	SPI Master data register. Accesses TX (write) and RX (read) FIFO buffers, both two bytes deep.
0xFB	SPIDLY	7:0	0x00	R/W	

	Csn_dly	7:4	0x0	R/W	SPI CSN delay counter enable setting. SPI CSN delay time calculation, please reference to SPI CSN delay time output select. Only using when CSN enable
	Gap_dly	3:0	0x0	R/W	Gap delay counter enable setting. Gap delay time calculate. Please reference to the gap delay time configuration.
0xF2	SPITEST	7:0	0xF0	R/W	SPI Master TEST REGISTER
	Msk_tx_underflow	7	1	R/W	1: Disable TX FIFO underflow flag when TX FIFO is empty, read again 0: Enable TX FIFO underflow flag when TX FIFO is empty, read again
	Msk_tx_overflow	6	1	R/W	1: Disable TX FIFO overflow when TX FIFO is full, write again 0: Enable TX FIFO overflow when TX FIFO is full, write again
	Msk_rx_underflow	5	1	R/W	1: Disable RX FIFO underflow flag when RX FIFO is empty, read again 0: Enable RX FIFO underflow flag when RX FIFO is empty, read again
	Msk_rx_overflow	4	1	R/W	1: Disable RX FIFO overflow when RX FIFO is full, write again 0: Enable RX FIFO overflow when RX FIFO is full, write again
	Tx_underflow_flag	3	0	R	1: TX FIFO underflow flag when TX FIFO is empty, read again Write this bit, clear the flag signal
	Tx_overflow_flag	2	0	R	1: TX FIFO overflow flag when TX FIFO is overflow, write again Write this bit, clear the flag signal
	Rx_underflow_flag	1	0	R	1: RX FIFO underflow flag when RX FIFO is empty, read again Write this bit, clear the flag signal
	Rx_overflow_flag	0	0	R	1: RX FIFO overflow flag when RX FIFO is overflow, write again Write this bit, clear the flag signal
0xE4	SPI_RESYNC_DLY	7:0	0x10	R/W	SPI re-synchronous time, only 2-wire mode

The SPI Master is configured through SPIMCON0 and SPIMCON1. It is enabled by setting SPIMCON0 [0] to ‘1’. The SPI Master supports all four SPI modes, selected by SPIMCON0[2] and SPIMCON0[1]. The bit wise data order per byte on MMISO/MMOSI is defined by SPIMCON0 [3]. MSCK can run on one of six predefined frequencies in the range of 1/2 to 1/64 of the MCU clock frequency, as defined by SPIMCON0[6]down to SPIMCON0[4]. After transferred one byte can generate interrupt (MSDONE), unless they are masked by their respective bits in SPIMSTAT [7:4]. SPIMDAT accesses both the TX (write) and the RX (read) FIFOs, which are two bytes deep. The FIFOs are dynamic and can be refilled according to the state of the status flags: “FIFO ready” means that the FIFO can accept data.“Data ready” means that the FIFO can provide minimum one byte.Four different sources can generate interrupt, unless they are masked by their respective bits in SPIMCON1, SPIMSTAT reveals which sources are active.

The gap delay configuration:

The SPI peripheral supports re-synchronization, so you can use gap delay to generate re-synchronous time by setting the value of gap delay count register (gap: 05h). The delay time is calculated by using the following formula:

$$\text{Gap delay time} = ((1/\text{system clock}) * \text{gap}) * 2;$$

4'h0: No gap delay active.

$$4'h1: \text{Gap delay} = ((1/16) * 1) * 2 = 125\text{ns};$$

$$4'hf: \text{Gap delay} = ((1/16) * 15) * 2 = 1.875\mu\text{s}$$

The CSN delay time configuration:

The SPI master supports adjustable SPI CSN delay (when csn_enable register enabled) before first byte transfer. The configuration register is SPIDLY and the formula is:

$$\text{SPI CSN delay time} = ((1/\text{system clock}) * \text{csndly}) * 2;$$

4'h0: No csn delay active.

$$4'h1: \text{CSN delay} = ((1/16) * 1) * 2 = 125\text{ns};$$

$$4'hf: \text{CSN delay} = ((1/16) * 15) * 2 = 1.875\mu\text{s}$$

The gap delay time and csn delay time is configured by above formula, in fig.10.3.

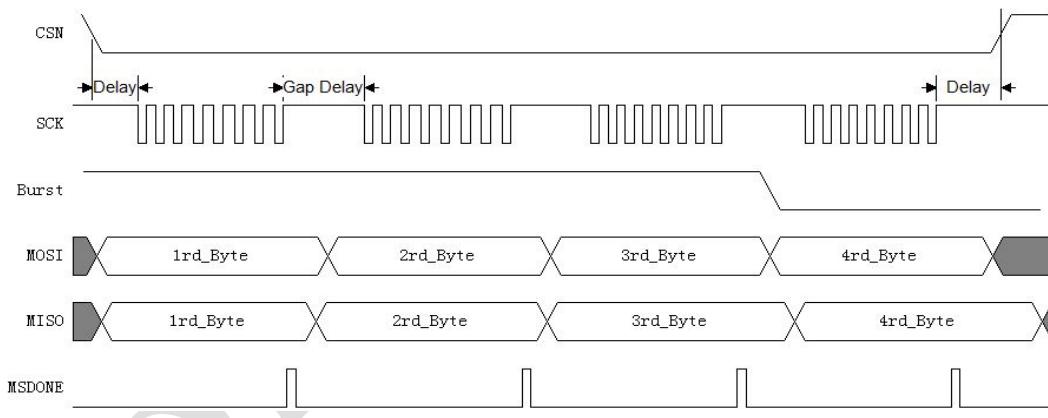

Fig.10.3 4wire SPI data transfer timing

10.3.2 Re-Synchronize the Interface (2-wire)

If the mouse controller and the mouse sensor get out of synchronization, then the data either written or read from the registers will be incorrect. To solve this issue, mouse sensors have different solutions. One of them is trying to toggle the SPI CLK line from high to low for at least Tresync period, this period is configured by the SPI_RESYNC_DLY register, and then toggle it from low to high to wait at least Tsiwtt period to satisfy re-synchronization condition, Tsiwtt is controlled by software.

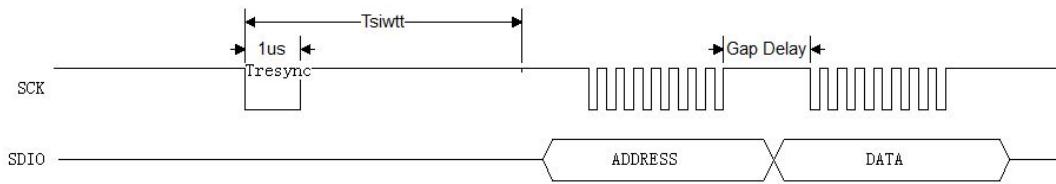

Fig.10.4 Re-synchronous the interface

10.3.3 3-wire SPI data transfer timing

HS6206 support two mode 3-wire mode SPI operations, one is with CSN signal, MOSI is in-out data line, burst function is familiar to the 4-wire function. Interrupt (MSDONE) is generated after 1 bytes transfer completed, for example the Fig. 10.5. Another is operation withoutCSN, the SPI Master function does not generate any chip select signal (CSN). The programmer typically uses another programmable digital I/O to act as chip selects for one or more external SPI Slave devices, in Fig.10.6.

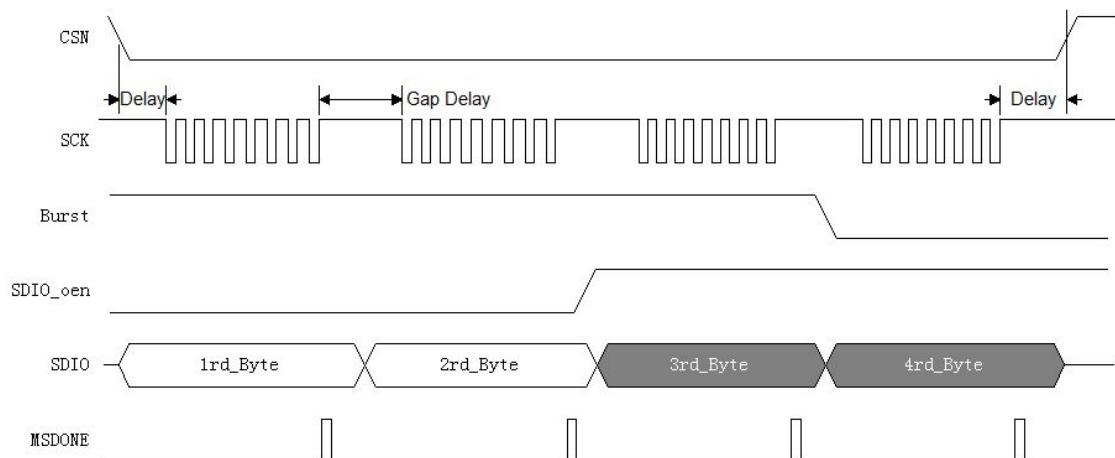

Fig.10.5 3wire SPI data transfer timing with CSN and MOSI is bidirectional port

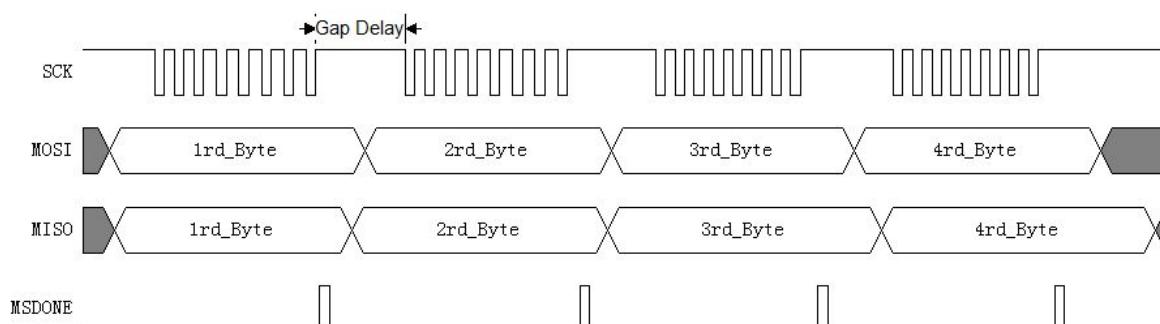

Fig.10.6 3wire SPI data transfer timing without CSN, software can configure CSN.

10.3.4 SPI slave

The following registers control the SPI slave:

Address (Hex)	Name/mnemonic	Bit	Reset Value	Type	Description
0xBC	SPISCON	6:0	0x70	R/W	SPI Slave configuration register
	maskIrqCsnHigh	6	1	R/W	1: Disable interrupt when SCSN goes high. 0: Enable interrupt when SCSN goes high
	maskIrqCsnLow	5	1	R/W	1: Disable interrupt when SCSN goes low. 0: Enable interrupt when SCSN goes low
	maskIrqSpiSlaveDone	4	1	R/W	1: Disable interrupt when SPI Slave is done with the current SPI transaction. 0: Enable interrupt when SPI Slave is done with the current SPI transaction.
	Dataorder	3	0	R/W	Data order (bit wise per byte) on serial output and input (SMOSI and SMISO respectively). 1: LSBit first, MSBit last. 0: MSBit first, LSBit last.
	Clockpolarity	2	0	R/W	Defines the SPI Master's operating mode together with SPISCON0 1: SSCK is active 'low'. 0: SSCK is active 'high'.
	Clockphase	1	0	R/W	Defines the SPI Slave's operating mode together with SPIRCON0 1: Sample on trailing edge of SSCK, shift on leading edge. 0: Sample on leading edge of SSCK, shift on trailing edge.
	Spi_en	0	0	R/W	1: SPI Slave is enabled. 0: SPI Slave is disabled. Please make sure that after the Spi_en is enabled, the value of Clockpolarity and Clockphase cannot be changed.
0xBE	SPISTAT	6:0	0x00	R	SPI Slave status register
	Tx_buffer_status	6	0	R	0: Location available in TX buffer. 1: TX buffer full. Cleared when the cause is removed.
	Csnhigh	5	0	R	Interrupt source: 1: Positive edge of SCSN detected 0: Positive edge of SCSN not detected. Cleared when read.
	Csnlow	4	0	R	Interrupt source: 1: Negative edge of SCSN detected 0: Negative edge of SCSN not detected. Cleared when read.

	<reserved>	3:1	-	R	
	Spi_done	0	0	R	Interrupt source: 1: SPI Slave done with an SPI transaction. 0: SPI Slave not done with an SPI transaction. Cleared when read.
0xBF	SPISDAT	7:0	0x00	R/W	SPI Slave data register. Accesses TX (write) and RX (read) buffers.

The SPI slave is configured through SPISCON. It is enabled by setting SPISCON.0 to '1'. The SPI Slave supports all four SPI modes, selected by SPISCON.2 and SPISCON.1. The bit wise data order per byte on SMISO/SMOSI is defined by SPISCON.3. After transferred one byte or CSN high/low edge can generate interrupt (SSDONE), unless they are masked by their respective bits in SPIRCON.

When an interrupt occurs, SPISSTAT provides information on what the source.

SPISDAT is used for data access in both directions. Prior to the first clock from the external SPI master, the MCU can write one byte to SPISDAT. For maximum data throughput, after the first byte has been transferred, software must ensure that there always are two bytes in the TX chain; one that is being transferred and another in the pipe.

10.3.5 SPI modes

The four different SPI modes are presented in tab. 10.1

SPI mode	clockPolarity	clockPhase	Clock shift edge		Clock sample edge	
0	0	0	Trialing	Falling	leading	Rising
1	0	1	leading	Rising	Trialing	Falling
2	1	0	Trialing	Rising	leading	Falling
3	1	1	leading	Falling	Trialing	Rising

Tab. 10.1 SPI modes

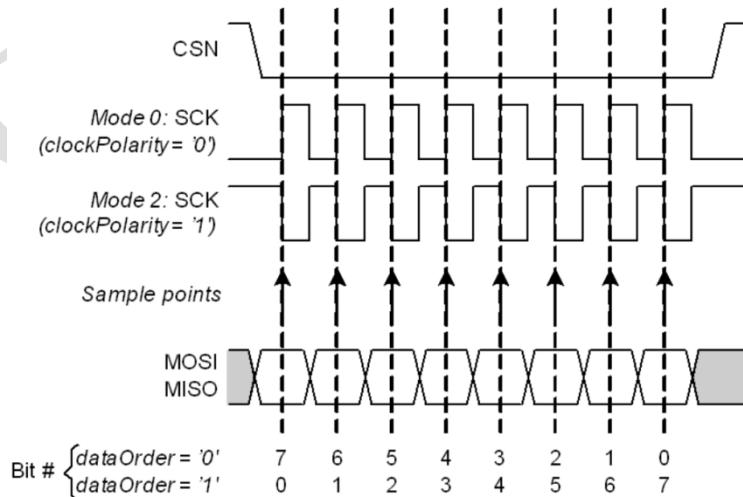

Fig.10.7 SPI Modes 0 and 2: clockPhase = '0'. One byte transmission

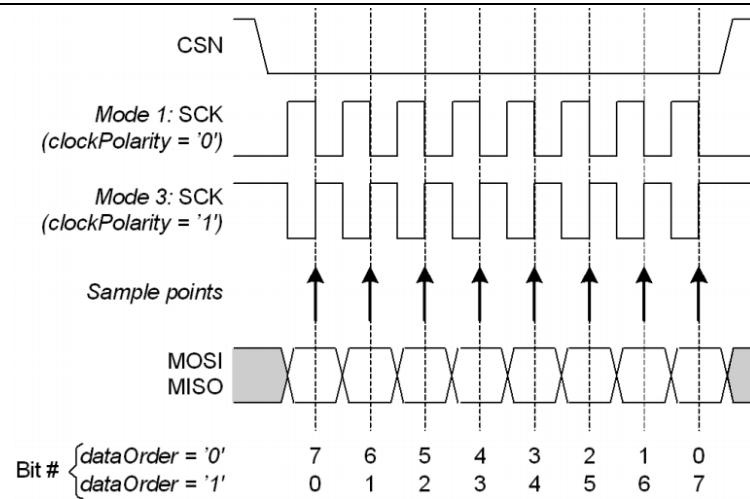

Fig.10.8 SPI Modes 1 and 3: *clockPhase = '1'*. One byte transmission

11 Timer 0 and Timer 1

The HS6206 contain two 16-bit timer/counters, Timer 0 and Timer 1 which compatible to standard 8051. In the “timer mode”, timer registers are incremented every system 1/12 clock period, when appropriate timer is enabled. In the “countermode” the timer registers are incremented every falling transition on their corresponding input pins: T0 or T1. The input pins are sampled every system clock period.

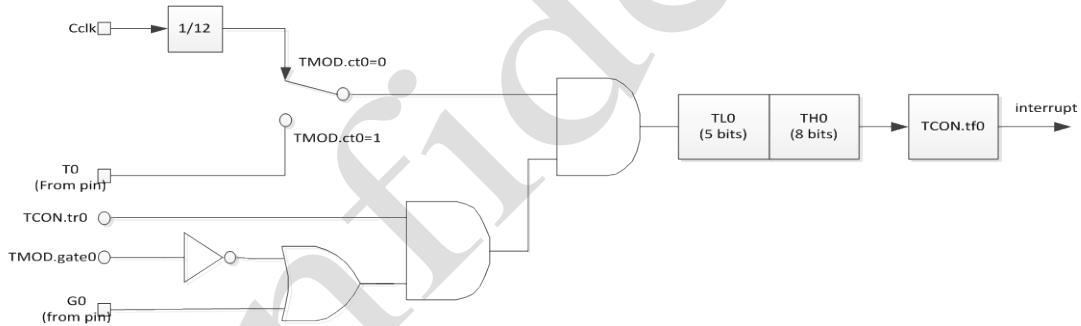

11.1 Timer 0

11.1.1 Mode 0

In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all 1's to all 0's, it sets the timer overflow flag TCON.tf0. The overflow flag TCON.tf0 then can be used to request an interrupt.

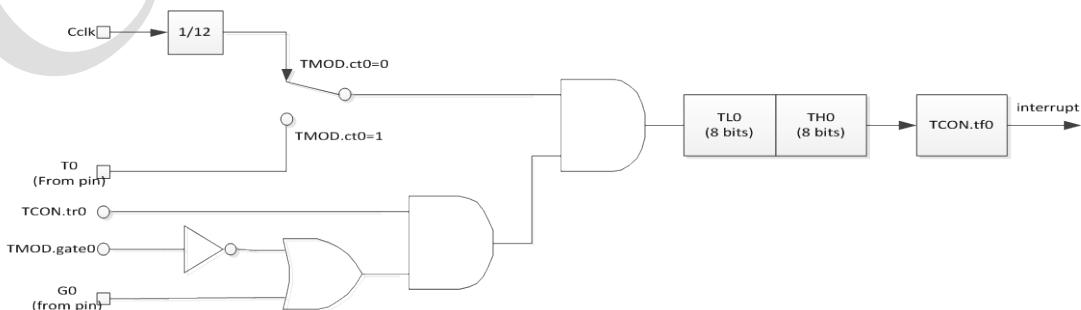

The counted input is enabled to the timer when TCON.tr0=1 and either TMOD.gate0=0 or G0=1 (setting TMOD.gate0=1 allows the timer 0 to be controlled by external input G0, to facilitate pulse width measurements).

The 13-bit register consists of all 8 bits of TH0 and the lower 5 bits of TL0. The upper 3 bits of TL0 are indeterminate and should be ignored. Setting the run flag (TCON.tr0) does not clear the registers.

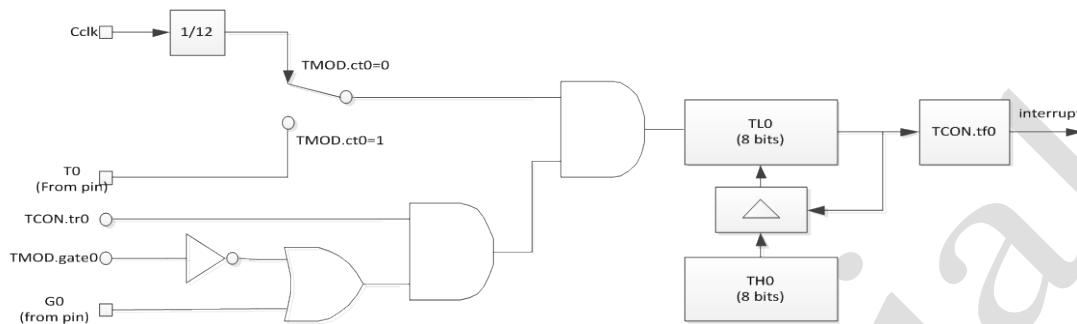

11.1.2 Mode 1

Mode 1 is the same as mode 0, except that the timer register is run with all 16 bits. Mode 1 is shown in figure below.

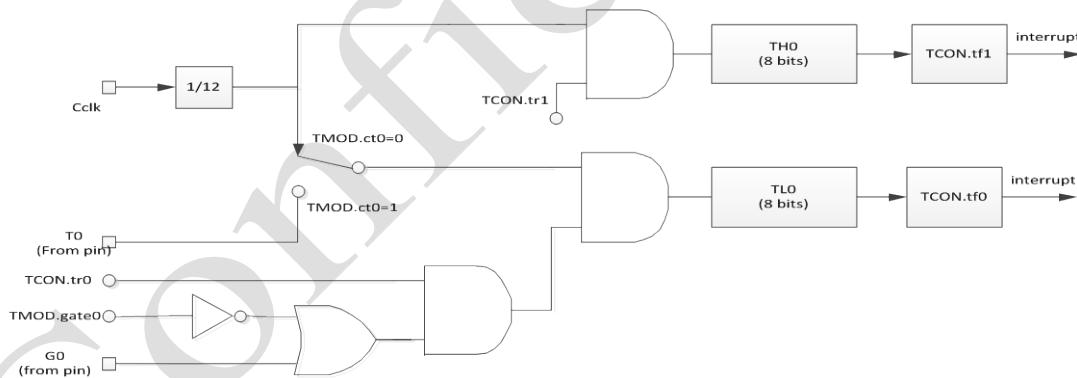

11.1.3 Mode 2

Mode 2 configures the timer register as an 8-bit counter (TL0) with automatic reloads as shown in figure below. Overflow from TL0 not only sets TCON.tf0, but also reloads TL0 with the contents of TH0, which is preset by software. The reload leaves TH0 unchanged.

11.1.4 Mode 3

Timer 0 in Mode 3 establishes TL0 and TH0 as two separate counters. The logic for Mode 3 on Timer 0 is shown in figure below. TL0 uses the Timer 0 control bits: TCON.tr0, TMODE.gate0, TCON.ct0, TCON.tf1 and G0. TH0 is locked into a timer function (counting machine cycles) and uses the TCON.tr1 and TCON.tf1 flags from Timer 1 and controls Timer 1 interrupt. Mode 3 is provided for applications requiring an extra 8-bit timer/counter. When Timer 0 is in Mode 3, Timer 1 can be turned off by switching it into its own Mode 3 or can still be used by the serial channel as a baud rate generator or in any application where interrupt from Timer 1 is not required.

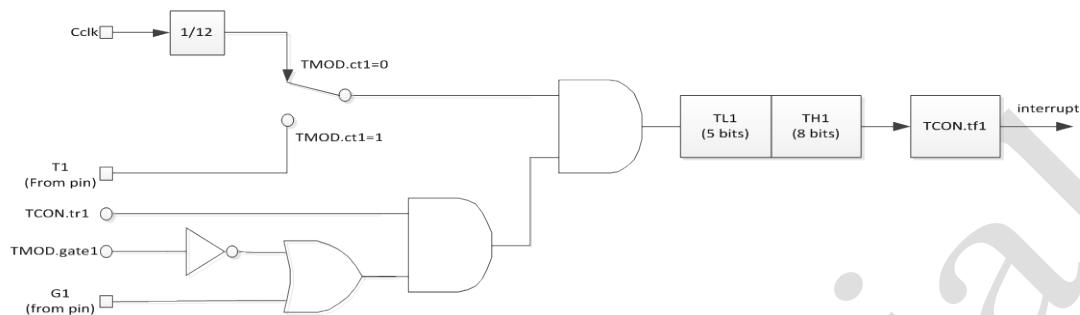

11.2 Timer 1

11.2.1 Mode0

In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all 1's to all 0's, it sets the timer overflow flag TCON.tf1. The overflow flag TCON.tf1 then can be used to request an interrupt.

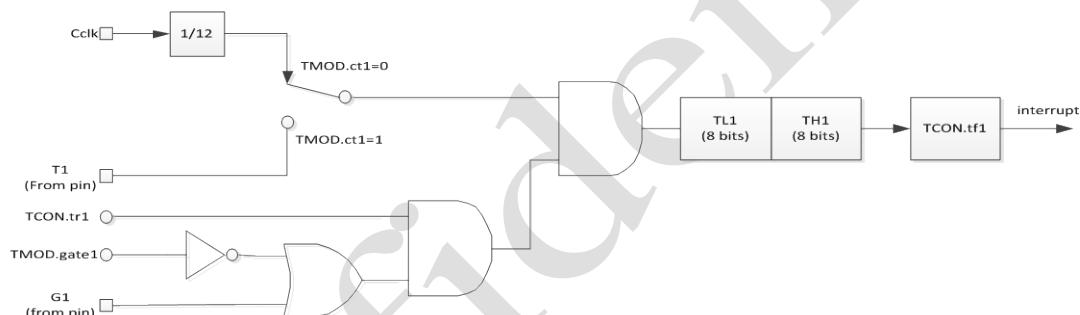

The counted input is enabled to the timer when TCON.tr1=1 and either TMOD.gate1=0 or G1=1 (setting TMOD.gate1=1 allows the timer 0 to be controlled by external input G1, to facilitate pulse width measurements).

The 13-bit register consists of all 8 bits of TH1 and the lower 5 bits of TL1. The upper 3 bits of TL1 are indeterminate and should be ignored. Setting the run flag (TCON.tr1) does not clear the registers.

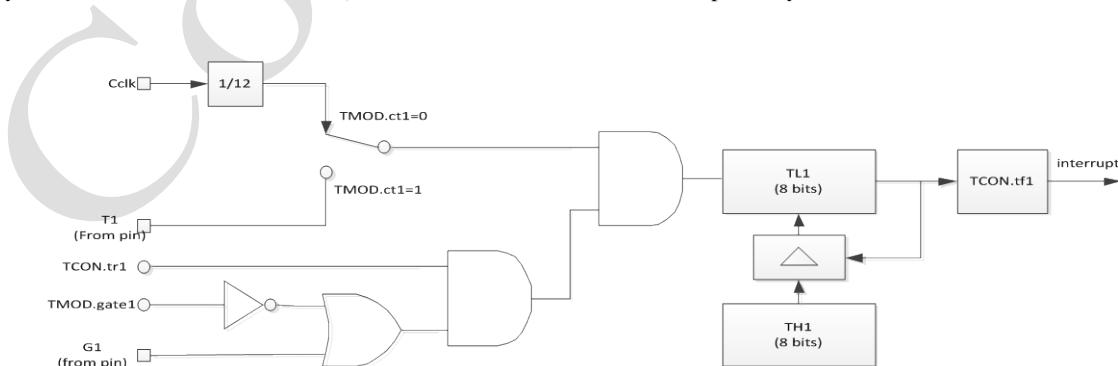

11.2.2 Mode1

Mode 1 is the same as mode 0, except that the timer register is run with all 16 bits. Mode 1 is shown in figure below.

11.2.3 Mode2

Mode 2 configures the timer register as an 8-bit counter (TL1) with automatic reloads as shown in figure below. Overflow from TL1 not only sets TCON.tf1, but also reloads TL1 with the contents of TH1, which is preset by software. The reload leaves TH1 unchanged.

11.2.4 Mode3

Timer 1 in mode 3 simply holds its count. The effectis the same as setting TCON.tr1=0.

11.3 SFR registers

11.3.1 Timer/Counter control register – TCON

TCONregister reflects the current status of MCU Timer 0 and Timer 1 and it is used to control the operation of these modules.

TCON(RW) 0x88

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit0

Confidential

12 Timer 2

Timer 2 is a complex 16-bit timer, which could support PWM function. It is used for all kinds of digital signal generation and event capturing like pulse generation, pulse width modulation, pulse width measuring etc. Timer 2 in combination with the compare/capture/reload registers allows the following modes:

- ✚ Reload: modulation of timer2 cycle time
- ✚ Capture: up to 4 high speed inputs with 0.75 μ sec resolution (MCU is clocked on 16MHz)
- ✚ Compare: up to 4 PWM signals with 65535 steps at maximum and 0.75 μ sec resolution

12.1 Timer 2 operate

The timer 2, which is a 16-bit-wide register, can operate as timer, event counter, or gated timer.

12.1.1 Timer Mode

Timer mode is invoked by setting the t2i0=1 and t2i1=0 in the T2CONregister. In this mode, the count rate is derived from the clock input.

Timer 2 is incremented every 12 or 24 clock cycles depending on the 2:1 pre-scale. The pre-scale mode is selected by bit t2ps of T2CONregister. When t2ps=0, the timer counts up every 12 clock cycles, otherwise every 24 cycles.

12.1.2 Event Counter Mode

This mode is invoked by setting the t2i0=0 and t2i1=1 in the T2CONregister.

In this mode, Timer 2 is incremented when external signal T2 changes its value from 1 to 0. The T2input is sampled at every rising edge of the clock. Timer 2 is incremented in the cycle following the one in which the transition was detected. The maximum count rate is 1/2 of the clock frequency.

12.1.3 Gated Timer Mode

This mode is invoked by setting the t2i0=1 and t2i1=1 in the T2CONregister.

In this mode, Timer 2 is incremented every 12 or 24 clock cycles (depending on T2CON t2ps flag). Additionally, it is gated by the external signal T2. When T2=0, Timer 2 is stopped. The T2 input is sampled into a flip-flop and then it blocks Timer 2 from incrementing.

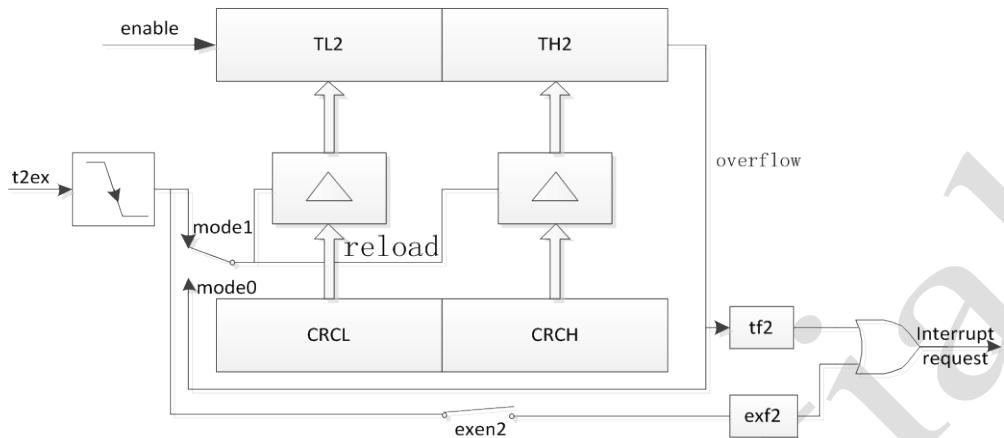

12.2 Reload Function

A 16-bit reload from the CRC register can be done in two modes:

1、Reload Mode 0: Reload signal is generated by Timer 2 overflow (auto reload).

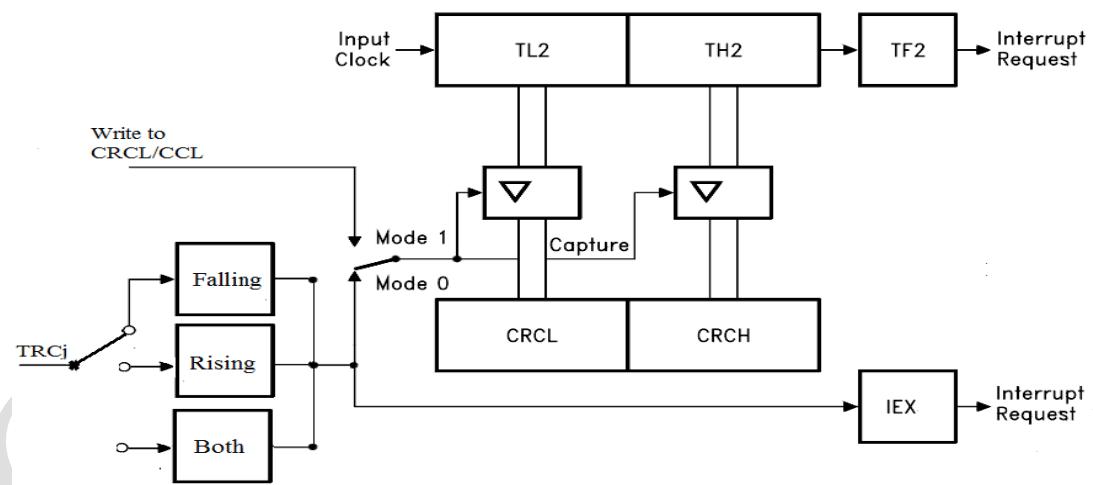

2、Reload Mode 1: Reload signal is generated by negative transition at t2ex.

Note: t2ex is connected to an internal clock signal which is half frequency of CLKLF.

12.3 Capture Function

Each of the three compare or capture registers CC1 to CC3 and the CRC register can be used to latch the current 16-bit value of the timer 2 registers TL2 and TH2. Two different modes are provided for this function. In mode 0, an external event latches the timer 2 contents to a dedicated capture register. In mode 1, a capture will occur upon writing to the low order byte of the dedicated 16-bit capture register.

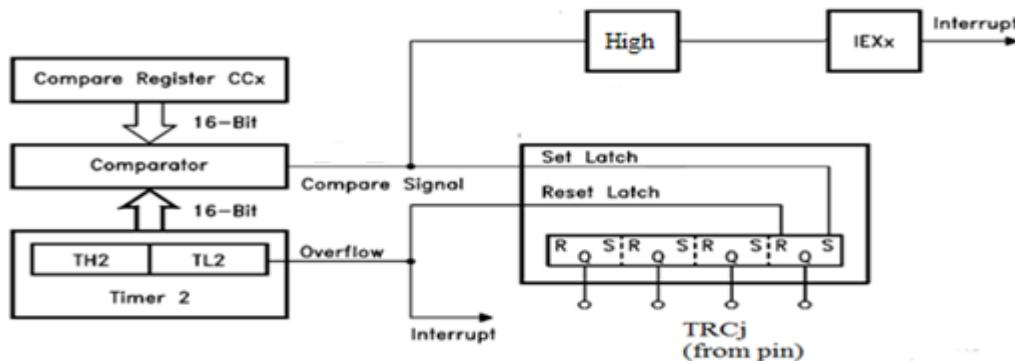

12.4 Compare Function

The compare function of a timer/register combination can be described as follows. The 16-bit value stored in a compare/capture register is compared with the contents of the timer register. If the count value in the timer register matches the stored value, an appropriate output signal is generated at a corresponding port pin.

12.4.1 Compare mode 0

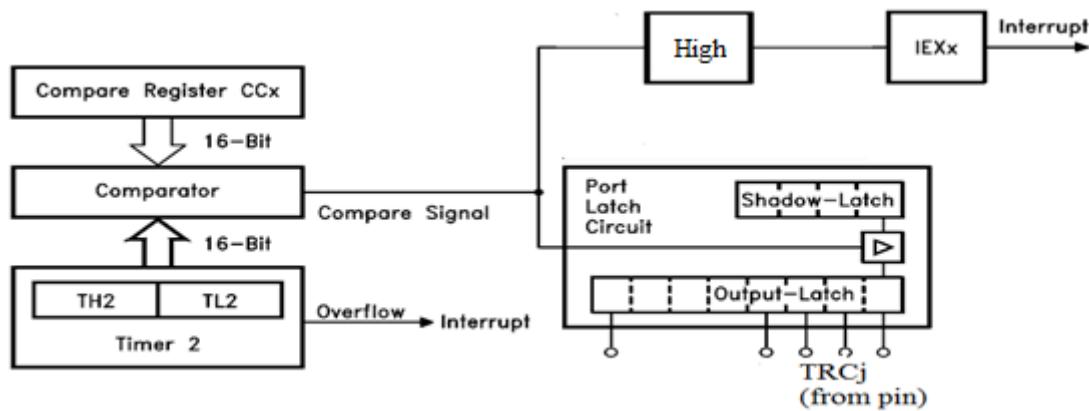

In mode 0, upon matching the timer and compare register contents, the output signal changes from low to high. It goes back to a low level on timer overflow. As long as compare mode 0 is enabled, the appropriate output pin is controlled by the timer circuit only, and not by the user. Writing to the port will have no effect. The functional diagram of a port latch in compare mode 0 is shown in figure below.

12.4.2 Compare mode 1

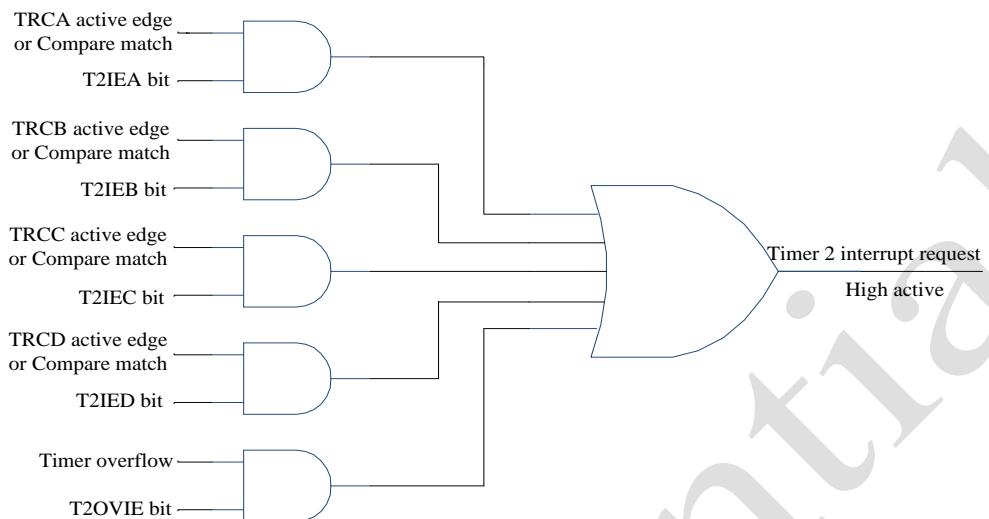

In compare mode 1, the software adaptively determines the transition of the output signal. It is commonly used when output signals are not related to a constant signal period (as in a standard PWM generation) but must be controlled very precisely with high resolution and without jitter. In compare mode 1, both transitions of a signal can be controlled. Compare outputs in this mode can be regarded as high speed outputs which are independent of the CPU activity.

If mode 1 is enabled, and the software writes to the appropriate output latch at the port, the new value will not appear at the output pin until the next compare match occurs. Thus, one can choose whether the output signal is to make a new transition (1-to-0 or 0-to-1, depending on the actual pin level) or should keep its old value at the time the timer 2 counter matches the stored compare value. The functional diagram of a timer/compare register/port latch configuration in compare mode 1 is shown in figure below.

12.5 Timer 2 Interrupt

Timer 2 generates a Timer 2 interrupt request from five sources, as shown in figure below.

12.6 SFR registers

12.6.1 Timer 2 control register – T2CON

T2CON register reflects the current status of Timer 2 and is used to control the Timer 2 operation.

T2CON (RW)

0xC8

13 Watchdog and RTC Wakeup Timer

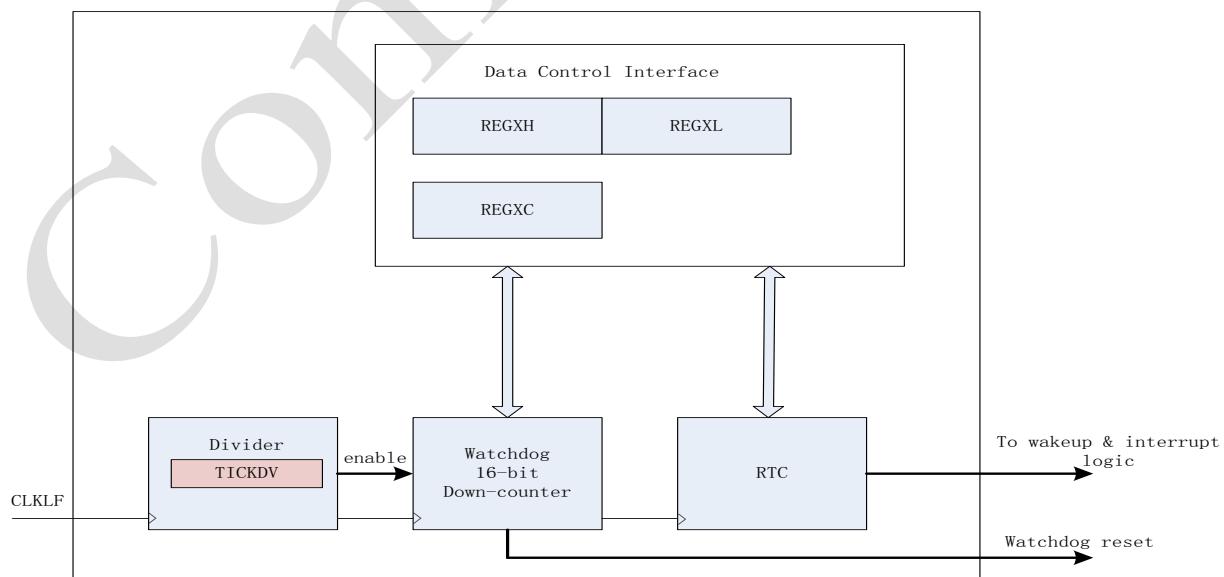

In order to achieve the lowest possible average current consumption, the processor clock can be stopped under firmware control. Operation can be resumed (wakeup) on external events like toggling of GPIO pins or from the internal RTCwakeup timer, USB or the RFIRQ.

In addition, a programmable watchdog timer can be enabled to reset the system if the software hangs.

13.1 Features

- 32 kHz operation
- Programmable 8-bit resolution for watchdog
- 16-bit range Watchdog
- Watchdog time range from 31.25us to 524s
- Watchdog can be disabled by a power-on reset, a reset from pin or watchdog reset, or possibly when the chip enters the Deep Sleep and the Register retention power-saving mode.
- 24-bit range RTCwakeup timer
- RTC time range from 31.25us to 524s
- RTCwakeup timer only disabled by a power-on reset or a reset from pin, or by software
- Compare with WU (IRQ), Resolution: 31.25 μ s.
- Capture with increased resolution: 125ns.

13.2 Block diagram

13.3 Functional description

13.3.1 Watchdog

The tick is an interval (in CLKLF periods) that determines the resolution of the watchdog. By default the tick is set to 125 μ s (4CLKLF cycles). The programmable range is from 31.25 μ s to 8ms. The tick is as accurate as the 32 kHz source. The tick is controlled by the TICKDV register.

After a reset, the default state of the Watchdog is disabled. The Watchdog is activated when WDTCNT have been written. The watchdog register is loaded by writing a 16-bit value (number of ticks) to the two 8-bit data registers (REGXH and REGXL) and then writing the correct op-code to the control register (REGXC). The watchdog counts down towards 0 and when 0 is reached the complete microcontroller, as well as the peripherals, are reset. A reset from the Watchdog will have the same effect as a power-on reset or a reset from pin except RTC Wakeup Timer module.

To avoid the reset, the software must reload WDTCNT sufficiently often. The Watchdog counter is updated with a new start value and restarted every time WDTCNT is written. If WDTCNT is loaded with 0x0000, The Watchdog WDTCNT= 0xffff is used.

The Watchdog timeout is given by:

$$\frac{WDTCNT * (TICKDV + 1)}{32000} [s]$$

If the Watchdog has been started, it can only be disabled by a power-on reset, a reset from pin or watchdog reset, or possibly when the chip enters the Deep Sleep and the Register retention power-saving mode. Please refer to WCON bit 5 in Indirect addresses and functions table.

Note

- 1: If the CLKLF has been disabled by software, the Watchdog counter retains the value before the CLKLF stops and the Watchdog is activated, and when the CLKLF is enabled, the Watchdog counts down from current value towards 0.
- 2: Only if the CLKLF is keep on, the Watchdog can be disabled by Watchdog reset or possibly when the chip enters the Deep Sleep and the Register retention power-saving mode.

13.3.2 RTC

RTC contains two registers that can be used for capturing timer values; one loaded at positive edge of the 32kHz clock and another register clocked by the MCU clock for better resolution. Both registers are updated as a consequence of an external event. RTC can also give an interrupt at predefined intervals due to value equality between the timer and a compare register. RTC ensures that the functions the interrupt is used for are awoken prior to the interrupt. A wakeup interrupt and RTC timer interrupt are the same interrupt, and known which one is interrupted, please refer to PWRDWN register bit 5 in 7.3.

The RTC timer is a 24-bit timer counting from zero and upwards at the rate of the 32kHz clock. When the RTC timer is equal to the

concatenation of RTCCMP1 and RTCCMP0, an RTC IRQ, also referred to as WU, is generated. There is an uncertainty of one CLKLF period, 30.25μs, from when the RTC is started or a new value is given to the RTC compare value registers and until the IRQ is given.

If compare mode 11 is used, the RTC IRQ will be given every $\frac{[RTCCMP1: RTCCMP0] + 1}{32000} (s)$ second.

The RTC compare value is updated every time RTCCMP1 or RTCCMP0 is written. This might give unwanted behavior if precaution is not taken when updating any of the variables. When new values are written to RTCCMP1 and RTCCMP0, the RTC IRQ should be disabled to prevent unwanted RTC IRQ.

The RTC counter uses the 32 kHz low frequency clock for the RTC timer, and the 32 kHz source must be enabled when using the RTC.

Note

- 1: The RTC can be disabled by a power-on reset or a reset from pin.
- 2: The RTC can be disabled by software only if the CLKLF is keep on.
- 3: If the CLKLF has been disabled by software, the RTC timer retains the value before the CLKLF stops and the RTC is enabled, and when the CLKLF is enabled, the RTC timer counts up from current value.

Writing RTCCMP0 and RTCCMP1:

- Disable the RTC IRQ, until both registers have been written.

Reading RTCCPT0 and RTCCPT1:

- Disable The Radio IRQ until both registers have been read.

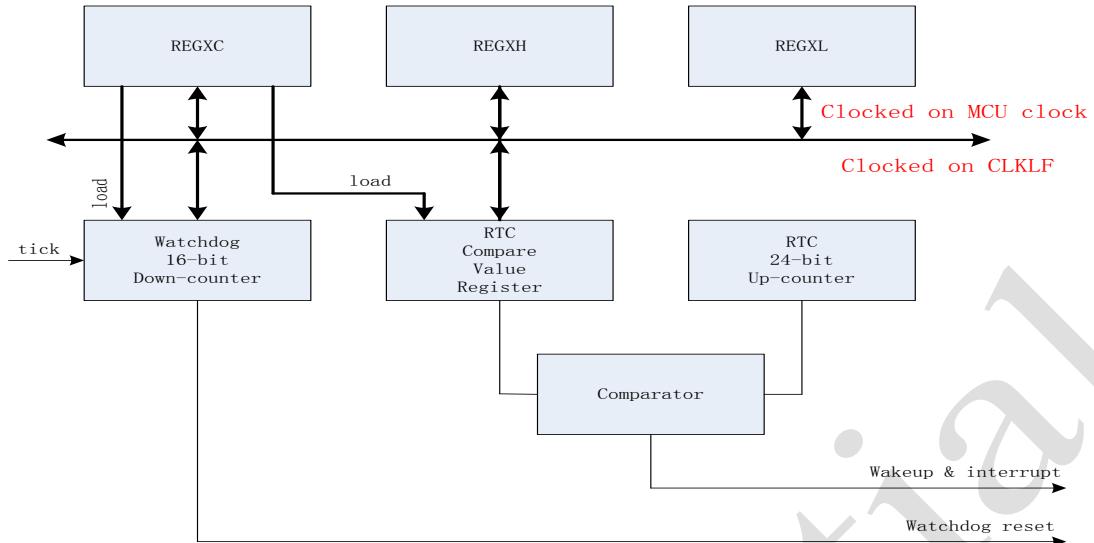

13.3.3 Programming interface to watchdog and RTC functions

RTC and Watchdog are controlled through three SFRs. The three registers, REGXH, REGXL and, REGXC, are used to interface the blocks running on the slow CLKLF clock. The 16-bit register REGXH:REGXL can be written or read as two bytes from the MCU.

Typical sequences are:

Write: Write REGXH, Write REGXL, Write REGXC

Read: Write REGXC, Read REGXH, Read REGXL

	5:4			Wakeup enable/disable and edge selection of P12(P12_trig)
	3:2			Wakeup enable/disable and edge selection of P11(P11_trig)
	1:0			Wakeup enable/disable and edge selection of P10(P10_trig) see Wakeup enable/disable and edge selection table
0011	15:12	---	---	Reserved, do not use
	11:10	RW	WCON2	Wakeup enable/disable and edge selection of P21(P21_trig)
	9:8			Wakeup enable/disable and edge selection of P20(P20_trig) see Wakeup enable/disable and edge selection table
	7:0	RW	RTCCPM1	RTC compare value register 1 Contains MSB partof the value to be compared to the timer value to generate RTC IRQ.
0100	15:0	RW	RTCCPM0	RTC compare value register 0 Contains Least significant partof the value to be compared to the timer value to generate RTC IRQ. Resolution: 30.25μs.
0101	15:6	-	WCON	Reserved, do not use
	5	RW		Watchdog module reset enable 0: If the CLKLF is keep on, the on-chip watchdog functionality will keep running. If the CLKLF is stopped or gated, the watchdog will halt. 1:If the CLKLF is keep on, the on-chip watchdog functionality will enter its reset state when the operational mode deep sleep or Register Retention is entered. If the CLKLF is stopped or gated, the watchdog will halt.

	4	RW		Trigger signal. When the MCU writes a '1' to this register field, RTC will capture the timer value. The value is stored in RTCCPT0 and RTCCPT1 low byte. An additional counter clocked by the MCU clock will at this point contain the number of MCU clock cycles from the previous positive edge of the 32.768 kHz clock (edge detect @ MCU clock). The value is stored in RTCCPT1 high byte.
	3	RW		1: Timer value is captured if required by an IRQ from the Radio (edge detect @MCU clock). The value is stored in RTCCPT0 and RTCCPT1 low byte. An additional counter clocked by the MCU clock will at this point contain the number of MCU clock cycles from the previous positive edge of the 32.768 kHz clock (edge detect @MCU clock). The value is stored in RTCCPT1 high byte. 0: Capture by Radio disabled.
	2:1	RW		Compare mode. 11: The RTCIRQ is assigned when the timer value is equal to RTC Timer. RTC ensures that the function for which the IRQ is intended, are all awoken prior to the RTC IRQ. When the RTC IRQ is assigned, the timer is reset. 10: Same as above, except that the RTC IRQ will not reset the timer. The timer will always wrap around at overflow. 0x: Compare disabled.
	0	RW		1: RTC is enabled. The clock to the RTC core functionality is running. 0: RTC is disabled. The clock to the RTC core functionality stands still and the timer is reset.
0110	15:0	R	RTCCPT0	Contains Least significant of the timer value at the time of the capture event. Resolution: 30.25 μs.
0111	15:8	R	RTCCPT1	Contains the value of the counter that counts the number of MCU clock cycles from the previous positive edge of the 32 kHz clock until the capture event. The counter value is truncated by one bit (LSBit). Resolution: 125 ns.
	7:0			Contains MSB part of the timer value at the time of the capture event. Resolution: 30.25 μs.
1000~1111	--	--	---	Reserve

Note: The default values are 16'h0 of all indirect address registers

14 GPIO Purpose IO Port and Pin Assignment

The IO pins of the HS6206 are default set to general purpose IO for the MCU. The numbers of available IOs are 18 for the HS6206. The IO pins provide the input, output and inout function to communicate with other components. To filter out high frequency input noise, digital filters are provided.

14.1 Block diagram

14.2 Features

- Digital filter for each pin
- Configurable Direction
- Configurable Drive Strength
 - Output buffer on, normal drive strength
 - Output buffer on, high drive strength
- Configurable Pull Up/Down
 - Input buffer on, no pull up/down resistor
 - Input buffer on, pull up resistor
 - Input buffer on, pull down resistor
 - Input buffer off

14.3 IO pin maps

The following conventions are used in all pin out maps:

- For dynamic connections and debug connections of digital peripheral blocks, the direction of each pin is indicated by 'in', 'out' or 'inout' next to the interface name.
- Normal mode, REG_DBG_SEL_0 and REG_DBG_SEL_1 registers must be set 8'h00.
- Debug mode, REG_DBG_SEL_0 and REG_DBG_SEL_1 registers set value except 8'h00. Port0 and Port1 are used for debug.

14.4 IO pin Description

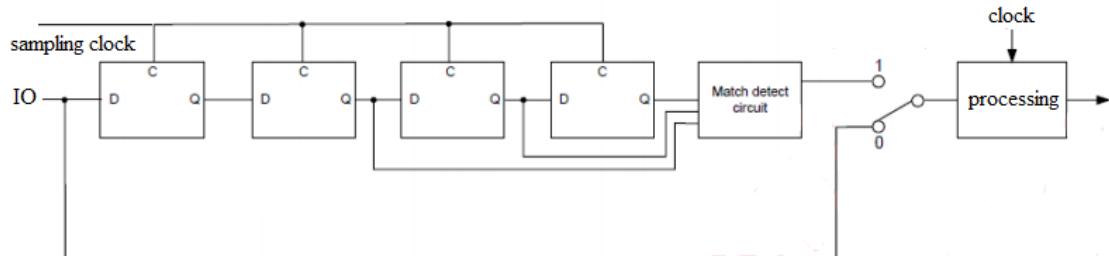

Pin	Description
P2.1	GPIO or output(SMISO) for slave SPI or output for PWM5
P2.0	GPIO or input(T2) for Timer2 event counter mode/gated mode or input(SCK) for slave SPI or output for PWM4
P1.7	GPIO or input(MMISO) for Master SPI
P1.6	GPIO or inout(MMOSI) for Master SPI
P1.5	GPIO or output(MSCK) for Master SPI
P1.4	GPIO or output(MCSN) for Master SPI
P1.3	GPIO or input(G1) for Timer1 to facilitate pulse widthmeasurement or input(SMOSI) for slave SPI or output PWM3
P1.2	GPIO or input(T1) for Timer1 counter mode or input(SCSN) for slave SPI
P1.1	GPIO or input(GPINT2) for external interrupt
P1.0	GPIO or input(TRCD) for Timer2 capture mode or output for Timer2 compare mode or output(FMISO) for OTP slave SPI or input (MISO_SF) for serial FLASH
P0.7	GPIO or input(TRCC) for Timer2 capture or output for Timer2 compare or input(FMOSI) for OTP slave SPI or output(MOSI_SF) for serial FLASH
P0.6	GPIO or input(TRCB) for Timer2 capture mode or output for Timer2 compare mode or input(FCSN) for OTP slave SPI or output(CSN_SF) for serial FLASH
P0.5	GPIO or input(TRCA) for Timer2 capture mode or output for Timer2 compare mode or input(FSCK) for OTP slave SPI or output(SCK_SF) for serial FLASH
P0.4	GPIO or input(RXD) for UART or output for PWM2
P0.3	GPIO or output(TXD) for UART or output for PWM1

P0.2	GPIO or output for PWM0
P0.1	GPIO or input(GPINT1) for external interrupt or input(G1) for Timer0 to facilitate pulse widthmeasurement
P0.0	GPIO or input(GPINT0) for external interrupt or input(T0) for Timer0 counter mode

14.5 Functional description

14.5.1 Digital filter

The input signal is sampled, and the level is determined when three matches occur. Block Diagram of Digital Filter is shown in figure below. Registers CFG_DFEN_Px control the enable/disable of digital filter for each I/O pin. To enable the digital filter, set the corresponding bit to 1.

14.5.2 General purpose IO pin functionality

This functionality is multiplexed with the functionality of the PortCrossbar module which takes control and configures the pins depending on the needs of the peripheral block connected.

The pins on the HS6206 are connected by default to a pin Multiplexer (MUX) that is connected to the GPIO registers of the MCU. Register Pn.m(n-port number, m-bitnumber) contains MCU GPIO data, PDIRn.mregister controls input/output direction and PCONN.mregister controls pin features drive strength and pull up/down resistors for each pin.

When the MCU enables one of the peripheral blocks of the HS6206 the pin MUX disconnects the MCU control of the pin and hands control over to the PortCrossbar module to set direction and pin features.

The HS6206 has one Pn.m, PnDIRm and PnCONn for each port. Pn.m and PnDIRm control only one parameter each, this means that a write/read operation to them controls/reads the status of the port directly. However, to control or read the features of a pin you use the PnCONm to write/read to one pin at a time. The PnCON register contains an address for the pin, information on whether it is an input or an output feature that is to be updated and the feature that is to be enabled.

For example: If four pins in port 1 are set as inputs with the pull up resistor enabled, then this is done with one write to P1DIR and four write operations to P1CON and only updating the pin address in P1CON for each write.

14.5.3 PortCrossbar functionality

The PortCrossbar sets up connections between the IO pins and the peripheral block of the device.

14.5.4 Dynamic allocation of pins

The PortCrossbar modifies connections dynamically based on run-time variations in system needs of the peripheral blocks of the device. This feature is necessary because the number of available pins is small compared to the combined IO needs of all the peripheral blocks. Consequently, there may be conflicting pin assignments. These are resolved through a set of priorities assigned to each peripheral block.

14.5.5 Dynamic pin allocation for digital blocks

Each digital peripheral block that needs an IO is represented in the pin out tables with the interface names of the block and the direction enforced on each pin. The priority of the blocks relative to potentially conflicting blocks is also shown. If the block is enabled, and no higher priority block is enabled, all the IO needs are granted.

14.5.6 Default pin allocation

If no peripheral blocks request IO, a default pinout as listed in the default column in the pin out maps are enabled. This means that all device pins are used for MCU GPIO. After reset, all pins are configured to be digital inputs. The features, direction and IO data on the pins are in this case controlled by registers PnCON, PnDIR and PnPn.

The default pin out also includes connections that are conditionally enabled based on the direction set for the pin. For example, if the P0DIR register sets pin P0.4 as an input, it can be used as a MCU GPIO input and as the UART receiver. If pin P0.3 is programmed as an output, it can be connected to the MCU as a GPIO output, but also have conditional output from the UART/TXD through an AND gate.

14.5.7 Debug functionality

The HS6206 has two debug select data registers (REG_DBG_SEL_0 and REG_DBG_SEL_1) for debug. REG_DBG_SEL_0 register controls Port0, and REG_DBG_SEL_1 controls Port1. Both the register default values are 8'h00. This means that all device pins are used for normal operation.

14.6 SFR registers

14.6.1 Control digital filter registers—CFG_DFEN_P0, CFG_DFEN_P1, CFG_DFEN_P2

Registers CFG_DFEN_Px control the enable/disable of digital filter for each I/O pin. To enable the digital filter, set the corresponding bit to 1.

14.6.4 The input and output options registers — P0CON,P1CON,P2CON

The input and output options of each pin are configured in the PnCON registers. The PnCON registers have to be written once per pin (one write operation to the PnCON register configures the input/output options of a selected pin in the port).

To read the current input or output options for a pin, you first need to perform a write operation to retrieve the desired bit address and option type (input or output).

For example, to read the output mode of pin P0.5: Write to P0CON with a bitAddr value of 101, a readAddr value of 1 and ainOut value of 0 (output). Then read from P0CON. The output mode of pin 5 is now found in bits 6:5 of the read data.

15 Interrupt

HS6206 has an advanced interrupt controller with 16 sources, as shown in Figure 1. The unit manages dynamic program sequencing based upon important real-time events as signaled from timers, the RF transceiver, pin activity, and so on.

15.1 Feature

- Interrupt controller with 16 sources and 4 priority levels
- Interrupt request flags available
- Interrupt from pin (configurable)

15.2 Block diagram

Block diagram of interrupt structure

15.3 Functional description

When an enabled interrupt occurs, the MCU vectors to the address of the interrupt service routine (ISR) associated with that interrupt, as listed in Table 1. The MCU executes the ISR to completion unless another interrupt of higher priority occurs.

Source	vector	Polarity	Description
IFP	0x0003	low/fall	Interrupt from pin GPINT0, GPINT1 or GPINT2 as selected by bits 3,4 or 5 in SFR INTEXP. Only one of the bits may be set at a time.
Tf0	0x000B	high	Timer 0 overflow interrupt
POFIRQ	0x0013	low/fall	Power Failure interrupt
tf1	0x001B	high	Timer 1 overflow interrupt
ri0	0x0023	high	Serial channel receive interrupt
ti0	0x0023	high	Serial channel transmit interrupt
tf2	0x002B	high	Timer 2 capture/compare or overflow interrupt
exf2	0x002B	high	Timer 2 external reload
RFRDY	0x0043	rise	RF SPI ready
RFIRQ	0x004B	low	RF interrupt
MSDONE	0x0053	fall/rise	Master SPI transaction completed
SSDONE	0x0053	fall/rise	Slave SPI transaction completed
X16IRQ	0x0053	fall/rise	XOSC16M started (X16IRQ)
USBWU	0x005B	rise	USB wakeup interrupt
USBIRQ	0x0063	low	USB interrupt
WU	0x006B	rise	Internal RTC Wakeup interrupt

HS6206 interrupt sources

Note: RFIRQ, X16IRQ and WU are not activated unless wakeup is enabled by WUCON (see section power and clock management).

15.4 SFR registers

Various SFR registers are used to control and prioritize between different interrupts.

The TCON, IRCON, IP0, IP1, IEN0, IEN1 and INTEXP are described in this section. In addition the TCON and T2CON are used, the description for these registers can be found in section Timers/Counters. S0CON is described in section Serial port.

15.4.1 Interrupt Enable 0 Register – IEN0

The IEN0 register is responsible for global interrupt system enabling/disabling and also Timer 0, 1 and 2, Port 0 and Serial Port individual interrupts enabling/disabling.

Address	Reset value	Bit	Description
0xA8	0x00	7	1: Enable interrupts. 0: all interrupts are disabled

		6	Not used
		5	1: Enable Timer2 (tf2/exf2) interrupt
		4	1: Enable Serial Port (ri0/ti0) interrupt
		3	1: Enable Timer1 overflow (tf1) interrupt
		2	1: Enable Power failure (POFIRQ) interrupt
		1	1: Enable Timer0 overflow (tf0) interrupt
		0	1: Enable Interrupt From Pin (IFP) interrupt

IEN0 register

15.4.2 Interrupt Enable 1 Register – IEN1

The IEN1 register is responsible for RF, SPI and Timer 2 interrupts.

Address	Reset value	Bit	Description
0xB8	0x00	7	1: Enable Timer2 external reload (exf2) interrupt
		6	Not used
		5	1: Internal wakeup (WU) interrupt enable
		4	1: USB interrupt enable
		3	1: USB wakeup interrupt enable
		2	1:SPI master/slave completed (MSDONE/SSDONE) interrupt enable, XOSC16M started (X16IRQ) interrupt enable
		1	1: RF (RFIRQ) interrupt enable
		0	1: RF SPI ready (RFRDY) interrupt enable

IEN1 register

2-Wire Master SPI and Slave SPI share the same interrupt line.

Address	Reset value	Bit	Description
0xA6	0x01	7:6	Not used
		5	1: Enable GP INT2 (from pin) to IFP
		4	1: Enable GP INT1 (from pin) to IFP
		3	1: Enable GP INTO (from pin) 0 to IFP
		2	Not used
		1	1: Enable Master SPI completed (MSDONE) interrupt
		0	1: Enable Slave SPI completed (SSDONE) interrupt

INTEXP register

15.4.3 Interrupt Priority Registers – IP0, IP1

The 17 interrupt sources are grouped into six priority groups. For each of the groups, one of four priority levels can be selected. They

can be selected by setting appropriate values in IP0 and IP1 registers.

The contents of the Interrupt Priority registers define the priority levels for each interrupt source according to the tables below.

Address	Reset value	Bit	Description
0xA9	0x00	7:6	Not used
		5:0	Interrupt priority. Each bit together with corresponding bit from IP1 register specifies the priority level of the respective interrupt priority group.

IP0 register

Address	Reset value	Bit	Description
0xB9	0x00	7:6	Not used
		5:0	Interrupt priority. Each bit together with corresponding bit from IP0 register specifies the priority level of the respective interrupt priority group.

IP1 register

Group	Interrupt bits	Priority group		
0	IP1[0], IP0[0]	IFP		RFRDY
1	IP1[1], IP0[1]	Timer 0 interrupt		RFIRQ
2	IP1[2], IP0[2]	POFIRQ		MSDONE/SSDONE/X16IRQ
3	IP1[3], IP0[3]	Timer 1 interrupt		USB wakeup
4	IP1[4], IP0[4]	ri0/ ti0		USB interrupt
5	IP1[5], IP0[5]	tf2/exf2		WU

Priority groups

IP1.x	IP0.x	Priority level
0	0	Level 0 (lowest)
0	1	Level 1
1	0	Level 2
1	1	Level 3 (highest)

Priority levels (x is the number of priority group)

15.4.4 Interrupt Request Control Registers – IRCON

The IRCON register contains interrupt request flags.

Address	Reset	Bit	Auto	Description
---------	-------	-----	------	-------------

	value		clear ^a	
0xC0	0x00	7		Timer 2 external reload (exf2) interrupt flag
		6	Yes	Timer 2 capture/compare or overflow (tf2) interrupt flag ^b
		5	Yes	Internal wakeup (TICK) interrupt flag
		4		USB interrupt flag
		3	Yes	USB wakeup interrupt flag
		2	Yes	Master/Slave SPI(MSDONE/SSDONE) , XOSC16M started (X16IRQ) interrupt flag
		1		RF (RFIRQ) interrupt flag
		0		RF SPI ready (RFRDY) interrupt flag

a: Auto clear means that the flag is cleared by hardware automatically when the corresponding service routine is vectored.

b: The flag will be cleared by hardware, but need to be clear the corresponding flag(refer to T2SR register) by software.

IRCON register

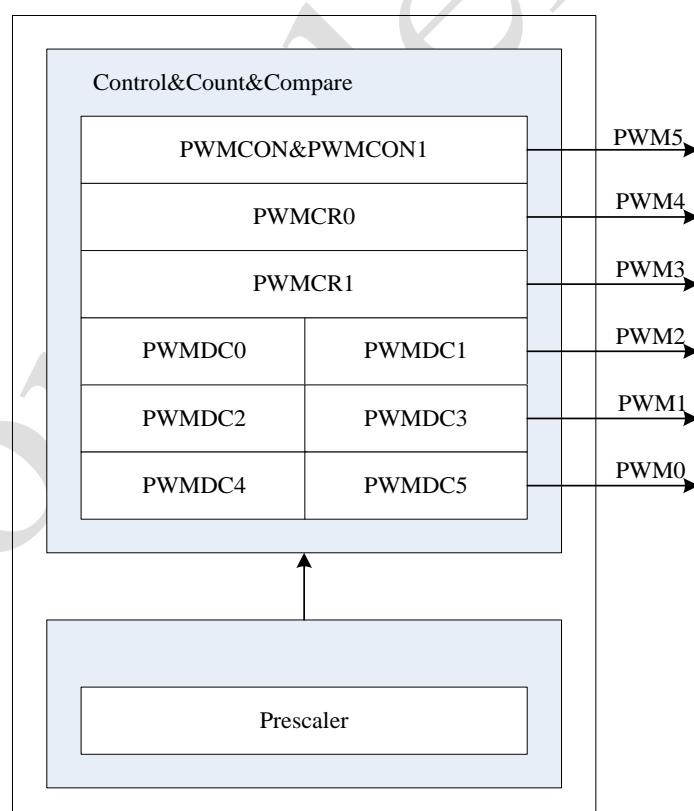

16 PWM

The HS6206 includes a six channel Pulse-Width Modulation (PWM) module. The six channels (PWM0, PWM1, PWM2,PWM3,PWM4 and PWM5) share a common enable/disable PWM and frequency pre-scale factor register,a period setting register, acontrolled Initial level register and a controlledactive levelregister, and have an individually controlled active level width register. The six PWM waveforms are the sameperiod, and can have differentInitial level, active level and inactivelevel width.

16.1 Features

- Six-channel output
- Frequency-range from 2KHz to 8 MHz
- Compact control using few registers for enabling,frequencypre-scale, period,Initial level, active level and inactive levelwidth

16.2 Block diagram

16.3 Functional description

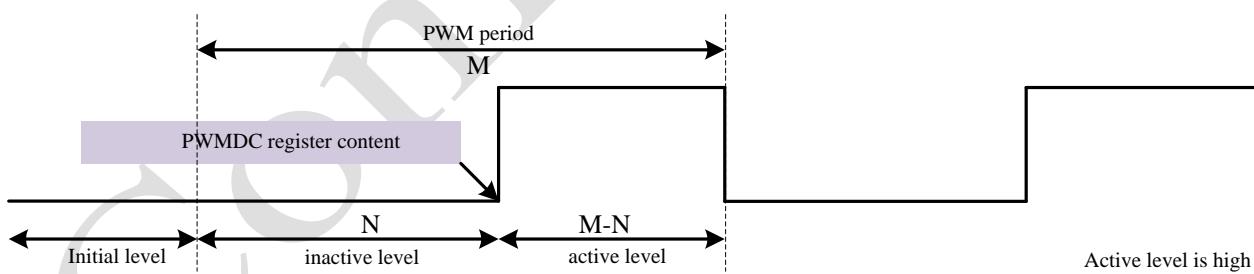

The HS6206 PWM is a six-channel PWM with a tenregisters interface. The first registerPWMCONenables or disables the PWM function and sets the PWM frequency pre-scale factor. The register PWMCON1 sets the PWM period length, which is the number of counter clock cycles for one PWM period. The registerPWMCR0 controls the PWM initial level. The register PWMCR1 controls the PWM active level. The registers, PWMDC0, PWMDC1, PWMDC2, PWMDC3, PWMDC4 and PWMDC5 control theinactive levelfor each PWM channel.

If you disable one of the six PWMs, the PWM outputpin retains the inactive level after the output is changed by matching the period.

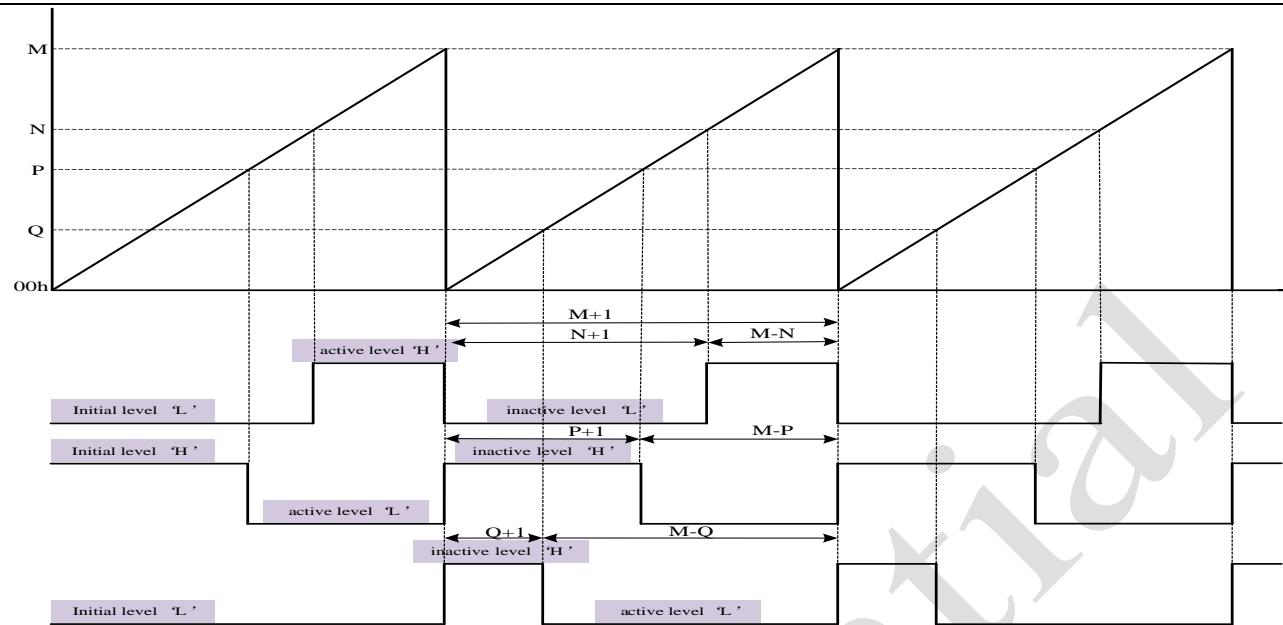

The following table shows how the PWMis controlled by the PWM SFR registers. Frequency-range is approximately2KHz-8MHz.

Item	Specification
Count source	1/1, 1/2, 1/8, 1/32of PWM clock (PWMCON)
Count operation	Increment
PWM waveform	PWM period: $1/\text{frq} \times (M + 1)$ Active level width: $1/\text{frq} \times (M - N)$ Inactive width: $1/\text{frq} \times (N + 1)$ frq: Frequency of count source M: Value set in PWMCON1 register N: Value set in PWMDCjregister ($j = 0, 1, 2, 3, 4, 5$) refer to the following figure
Selectable functions	Initial level selectable for each individual pin (PWMCR0) Active level selectable for each individual pin (PWMCR1)

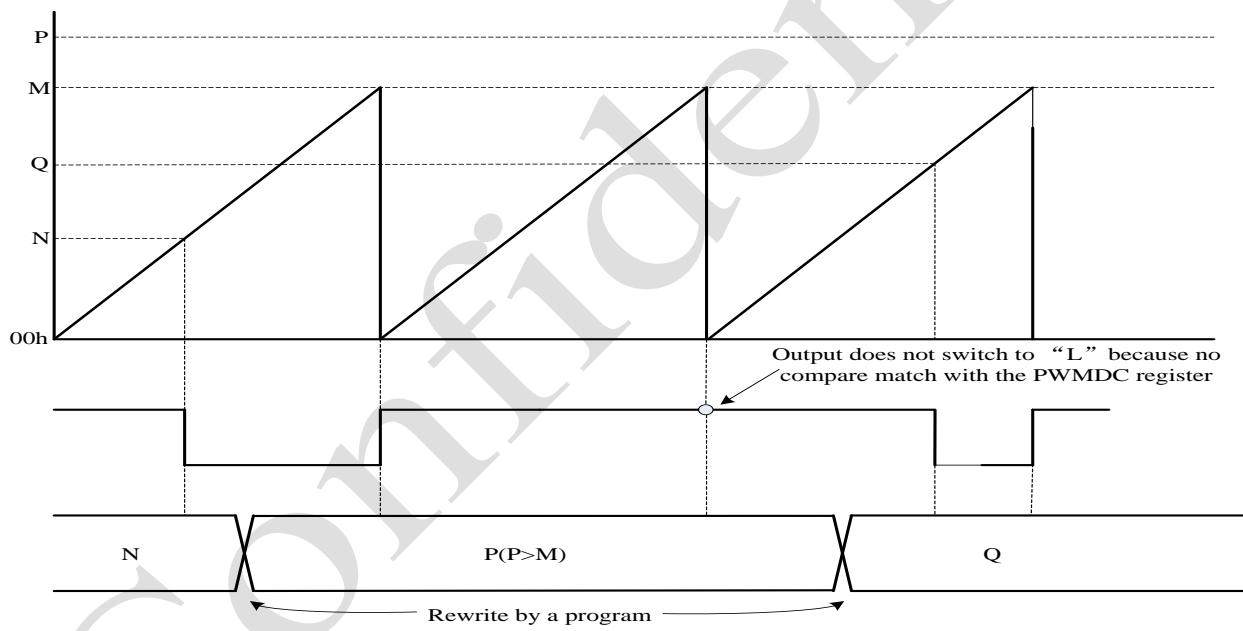

Upon matching PWMDC register contents, the output signal changes frominactive level toactive level. It goes back to inactive level bymatchingthe period (refer to the PWMCON1 registercontent).

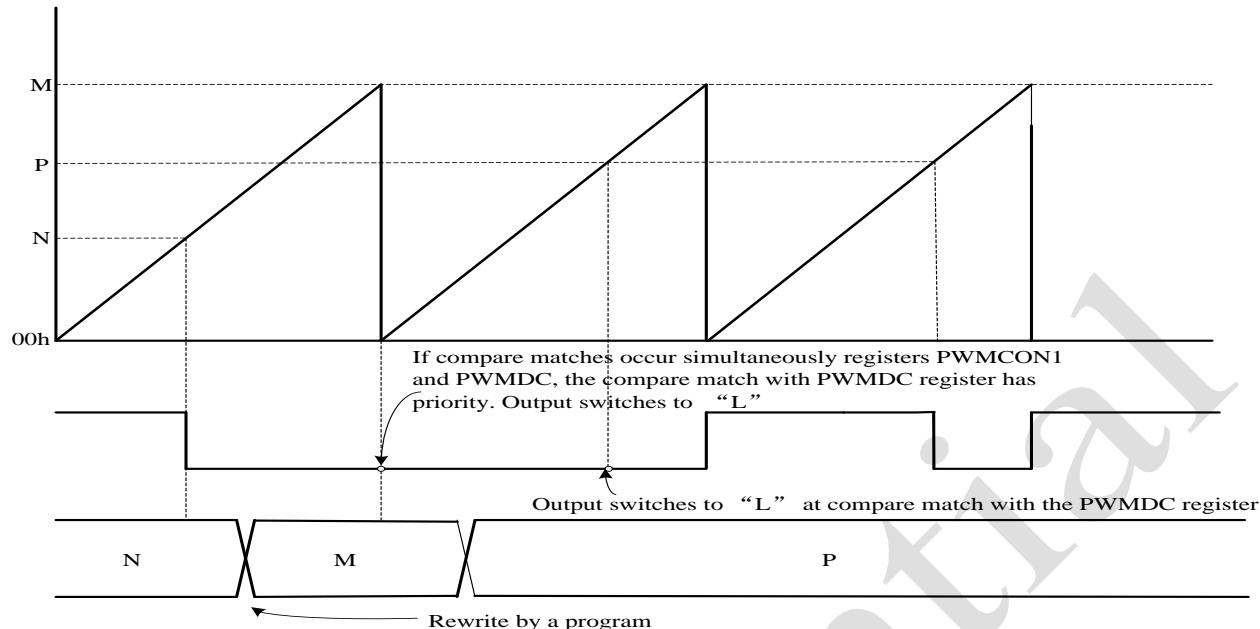

Operating example in PWM mode is shownin figure below.

Operating example in PWM mode is shown in figure below.

16.4 SFR registers

16.4.1 PWM control register—PWMCON

The PWMCON enables or disables the PWM function and sets the PWM frequency pre-scale factor.

PWMCON (RW)
